Preamble

Since 1980, the American College of Cardiology (ACC) and American Heart Association (AHA) have translated scientific evidence into clinical practice guidelines (guidelines) with recommendations to improve cardiovascular health. These guidelines, which are based on systematic methods to evaluate and classify evidence, provide a cornerstone for quality cardiovascular care. The ACC and AHA sponsor the development and publication of guidelines without commercial support, and members of each organization volunteer their time to the writing and review efforts. Guidelines are official policy of the ACC and AHA.

Intended Use

Practice guidelines provide recommendations applicable to patients with or at risk of developing cardiovascular disease. The focus is on medical practice in the United States, but guidelines developed in collaboration with other organizations may have a global impact. Although guidelines may be used to inform regulatory or payer decisions, their intent is to improve patients’ quality of care and align with patients’ interests. Guidelines are intended to define practices meeting the needs of patients in most, but not all, circumstances and should not replace clinical judgment.

Clinical Implementation

Guideline recommended management is effective only when followed by healthcare providers and patients. Adherence to recommendations can be enhanced by shared decision making between healthcare providers and patients, with patient engagement in selecting interventions based on individual values, preferences, and associated conditions and comorbidities.

Methodology and Modernization

The ACC/AHA Task Force on Clinical Practice Guidelines (Task Force) continuously reviews, updates, and modifies guideline methodology on the basis of published standards from organizations including the Institute of Medicine (1, 2) and on the basis of internal reevaluation. Similarly, the presentation and delivery of guidelines are reevaluated and modified on the basis of evolving technologies and other factors to facilitate optimal dissemination of information at the point of care to healthcare professionals. Given time constraints of busy healthcare providers and the need to limit text, the current guideline format delineates that each recommendation be supported by limited text (ideally, <250 words) and hyperlinks to supportive evidence summary tables. Ongoing efforts to further limit text are underway. Recognizing the importance of cost-value considerations in certain guidelines, when appropriate and feasible, an analysis of the value of a drug, device, or intervention may be performed in accordance with the ACC/AHA methodology (3).

To ensure that guideline recommendations remain current, new data are reviewed on an ongoing basis, with full guideline revisions commissioned in approximately 6-year cycles. Publication of new, potentially practice-changing study results that are relevant to an existing or new drug, device, or management strategy will prompt evaluation by the Task Force, in consultation with the relevant guideline writing committee, to determine whether a focused update should be commissioned. For additional information and policies regarding guideline development, we encourage readers to consult the ACC/AHA guideline methodology manual (4) and other methodology articles (5-8).
Selection of Writing Committee Members
The Task Force strives to avoid bias by selecting experts from a broad array of backgrounds. Writing committee members represent different geographic regions, sexes, ethnicities, races, intellectual perspectives/biases, and scopes of clinical practice. The Task Force may also invite organizations and professional societies with related interests and expertise to participate as partners, collaborators, or endorsers.

Relationships With Industry and Other Entities
The ACC and AHA have rigorous policies and methods to ensure that guidelines are developed without bias or improper influence. The complete relationships with industry and other entities (RWI) policy can be found at http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/relationships-with-industry-policy. Appendix 1 of the current document lists writing committee members’ relevant RWI. For the purposes of full transparency, writing committee members’ comprehensive disclosure information is available online at http://circ.ahajournals.org/lookup/suppl/doi:10.1161/CIR.0000000000000509/-/DC1. Comprehensive disclosure information for the Task Force is available at http://www.acc.org/guidelines/about-guidelines-and-clinical-documents/guidelines-and-documents-task-forces.

Evidence Review and Evidence Review Committees
When developing recommendations, the writing committee uses evidence-based methodologies that are based on all available data (4-7). Literature searches focus on randomized controlled trials (RCTs) but also include registries, nonrandomized comparative and descriptive studies, case series, cohort studies, systematic reviews, and expert opinion. Only key references are cited.

An independent evidence review committee (ERC) is commissioned when there are 1 or more questions deemed of utmost clinical importance that merit formal systematic review. This systematic review will strive to determine which patients are most likely to benefit from a drug, device, or treatment strategy and to what degree. Criteria for commissioning an ERC and formal systematic review include: a) the absence of a current authoritative systematic review, b) the feasibility of defining the benefit and risk in a time frame consistent with the writing of a guideline, c) the relevance to a substantial number of patients, and d) the likelihood that the findings can be translated into actionable recommendations. ERC members may include methodologists, epidemiologists, healthcare providers, and biostatisticians. When a formal systematic review has been commissioned, the recommendations developed by the writing committee on the basis of the systematic review are marked with “SR”.

Guideline-Directed Management and Therapy
The term guideline-directed management and therapy (GDMT) encompasses clinical evaluation, diagnostic testing, and pharmacological and procedural treatments. For these and all recommended drug treatment regimens, the reader should confirm the dosage by reviewing product insert material and evaluate the treatment regimen for contraindications and interactions. The recommendations are limited to drugs, devices, and treatments approved for clinical use in the United States.

Class of Recommendation and Level of Evidence
The Class of Recommendation (COR) indicates the strength of the recommendation, encompassing the estimated magnitude and certainty of benefit in proportion to risk. The Level of Evidence (LOE) rates the
quality of scientific evidence that supports the intervention on the basis of the type, quantity, and consistency of data from clinical trials and other sources (Table 1) (4-6).

Glenn N. Levine, MD, FACC, FAHA
Chair, ACC/AHA Task Force on Clinical Practice Guidelines
1. Introduction

The purpose of this focused update is to update the “2013 ACCF/AHA Guideline for the Management of Heart Failure” (9) (2013 HF guideline) in areas in which new evidence has emerged since its publication. For this update and future heart failure (HF) guidelines, the Heart Failure Society of America (HFSA) has partnered with the ACC and AHA to provide coordinated guidance on the management of HF.

The scope of the focused update includes revision to the sections on biomarkers; new therapies indicated for stage C HF with reduced ejection fraction (HFrEF); updates on HF with preserved ejection fraction (HFpEF); new data on important comorbidities, including sleep apnea, anemia, and hypertension; and new insights into the prevention of HF.

This focused update represents the second part of a 2-stage publication; with the first part having been published as the “2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure” (10), which introduced guidance on new therapies, specifically for the use of an angiotensin receptor–neprilysin inhibitor (ARNI) (valsartan/sacubitril) and a sinoatrial node modulator (ivabradine). That focused update was published concurrently with the European Society of Cardiology’s complete guideline, “2016 ESC Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure” (11).

1.1. Methodology and Evidence Review

To identify key data that influence guideline recommendations, the Task Force and members of the 2013 HF guideline writing committee reviewed clinical trials that were presented at the annual scientific meetings of the ACC, AHA, and European Society of Cardiology and other scientific meetings and that were published in peer-reviewed format from April 2013 through November 2016. The evidence is summarized in tables in the Online Data Supplement (http://circ.ahajournals.org/lookup/suppl/doi:10.1161/CIR.0000000000000509/-/DC2). All recommendations (new, modified, and unchanged) for each clinical section are included to provide a comprehensive assessment. The text explains new and modified recommendations, whereas recommendations from the previous guideline that have been deleted or superseded no longer appear. Please consult the full-text version of the 2013 HF guideline (9) for text and evidence tables supporting the unchanged recommendations and for clinical areas not addressed in this focused update. Individual recommendations in this focused update will be incorporated into the full-text guideline in the future. Recommendations from the prior guideline that remain current have been included for completeness, but the LOE reflects the COR/LOE system used when the recommendations were initially developed. New and modified recommendations in this focused update reflect the latest COR/LOE system, in which LOE
B and C are subcategorized for greater specificity (4-6). The section numbers correspond to the full-text guideline sections.

1.2. Organization of the Writing Group

For this focused update, representative members of the 2013 HF guideline writing committee were invited to participate. They were joined by additional invited members to form a new writing group, which is referred to as the 2017 HF focused update writing group. Members were required to disclose all RWI relevant to the data under consideration. The group was composed of experts representing general cardiologists, HF and transplantation specialists, electrophysiologists, pharmacists, and general internists. The 2017 HF focused update writing group included representatives from the ACC, AHA, and HFSA, as well as the American Academy of Family Physicians, American College of Chest Physicians, American College of Physicians, and International Society for Heart and Lung Transplantation.

1.3. Document Review and Approval

The focused update was reviewed by 2 official reviewers each nominated by the ACC, AHA, and HFSA; 1 reviewer each from the American Academy of Family Physicians, American College of Chest Physicians, and International Society for Heart and Lung Transplantation; and 19 individual content reviewers. Reviewers’ RWI information is published in this document (Appendix 2).

This document was approved for publication by the governing bodies of the ACC, AHA, and HFSA.

</tbody>
</table>

COR and LOE are determined independently (any COR may be paired with any LOE).

A recommendation with LOE C does not imply that the recommendation is weak. Many important clinical questions addressed in guidelines do not lend themselves to clinical trials. Although RCTs are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

* The outcome or result of the intervention should be specified (an improved clinical outcome or increased diagnostic accuracy or incremental prognostic information).

† For comparative-effectiveness recommendations (COR I and IIa; LOE A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

‡ The method of assessing quality is evolving, including the application of standardized, widely used, and preferably validated evidence grading tools; and for systematic reviews, the incorporation of an Evidence Review Committee.

COR indicates Class of Recommendation; ED, expert opinion; LD, limited data; LOE, Level of Evidence; NR, nonrandomized; R, randomized; and RCT, randomized controlled trial.
6. Initial and Serial Evaluation of the HF Patient

6.3. Biomarkers

Assays for BNP (B-type natriuretic peptide) and NT-proBNP (N-terminal pro-B-type natriuretic peptide), which are both natriuretic peptide biomarkers, have been used increasingly to establish the presence and severity of HF. In general, both natriuretic peptide biomarker values track similarly, and either can be used in patient care settings as long as their respective absolute values and cutpoints are not used interchangeably. Notably, BNP, but not NT-proBNP, is a substrate for neprilysin. Therefore, ARNI increases BNP levels (12) but not NT-proBNP levels (13). Note that the type of natriuretic peptide assay that has been performed must be considered during interpretation of natriuretic peptide biomarker levels in patients on ARNI. In 2 studies with ARNI, NT-proBNP levels were reduced (12, 14), with the reduction in 1 study being associated with improved clinical outcomes (12).

A substantial evidence base exists that supports the use of natriuretic peptide biomarkers to assist in the diagnosis or exclusion of HF as a cause of symptoms (e.g., dyspnea, weight gain) in the setting of chronic ambulatory HF (15-21) or in the setting of acute care with decompensated HF (22-30), especially when the cause of dyspnea is unclear. The role of natriuretic peptide biomarkers in population screening to detect incident HF is emerging (31-37). Elevated plasma levels of natriuretic peptide biomarkers are associated with a wide variety of cardiac and noncardiac causes (Table 2) (38-42). Obesity may be associated with lower natriuretic peptide concentrations, and this may modestly reduce diagnostic sensitivity in morbidly obese patients (42).

Because of the absence of clear and consistent evidence for improvement in mortality and cardiovascular outcomes (43-62), there are insufficient data to inform specific guideline recommendations related to natriuretic peptide–guided therapy or serial measurements of BNP or NT-proBNP levels for the purpose of reducing hospitalization or deaths in the present document.

Like natriuretic peptides, cardiac troponin levels may be elevated in the setting of chronic or acute decompensated HF, suggesting myocyte injury or necrosis (63). Troponins I and T respond similarly for acute coronary syndromes and acute decompensated HF. Elevations in either troponin I or T levels in the setting of acute HF are of prognostic significance and must be interpreted in the clinical context (64).

In addition to natriuretic peptides and troponins (65-67), multiple other biomarkers, including those of inflammation, oxidative stress, vascular dysfunction, and myocardial and matrix remodeling, have been implicated in HF (68-71). Biomarkers of myocardial fibrosis, soluble ST2 receptor, and galectin-3 are predictive of hospitalization and death and may provide incremental prognostic value over natriuretic peptide levels in patients with HF (72-74). Strategies that combine multiple biomarkers may
ultimately prove beneficial in guiding HF therapy in the future, but multicenter studies with larger
derivation and validation cohorts are needed (75, 76). Several emerging biomarkers await validation with
well-defined outcome measures and prognostic accuracy before they can reach the clinical arena (77-84).

This section categorizes the role of biomarkers into prevention, diagnosis, prognosis, and added
risk stratification to clarify evidence-based objectives of their use in clinical practice.

NEW: New data suggest that natriuretic peptide biomarker screening and early intervention may prevent HF.

In a large-scale unblinded single-center study (STOP-HF [The St Vincent’s Screening to Prevent Heart Failure]) (85), patients at risk of HF (identified by the presence of hypertension, diabetes mellitus, or known vascular disease [e.g., stage A HF]), but without established left ventricular systolic dysfunction or symptomatic HF at baseline, were randomly assigned to receive screening with BNP testing or usual primary care. Intervention-group participants with BNP levels of ≥50 pg/mL underwent echocardiography and were referred to a cardiovascular specialist who decided on further investigation and management. All patients received further coaching by a specialist nurse who emphasized individual risk and the importance of adherence to medication.
and healthy lifestyle behaviors. BNP-based screening reduced the composite endpoint of asymptomatic left ventricular dysfunction (systolic or diastolic) with or without newly diagnosed HF (85). Similarly, in another small, single-center RCT, accelerated up-titration of renin-angiotensin-aldosterone system antagonists and beta blockers reduced cardiac events in patients with diabetes mellitus and elevated NT-proBNP levels but without cardiac disease at baseline (86). Developing a standardized strategy to screen and intervene in patients at risk of HF can be difficult because of different definitions of HF risk, heterogeneity of prevalence in different populations, variable duration until clinical HF or left ventricular dysfunction develops, and variable interventions for risk factor modification or treatment. Further studies are needed to determine cost-effectiveness and risk of such screening, as well as its impact on quality of life (QoL) and mortality rate.

6.3.2. Biomarkers for Diagnosis: Recommendation

<table>
<thead>
<tr>
<th>Biomarkers: Recommendation for Diagnosis</th>

</tbody>
</table>

Natriuretic peptide biomarker testing in the setting of chronic ambulatory HF provides incremental diagnostic value to clinical judgment, especially when the etiology of dyspnea is unclear (15-21). In emergency settings, natriuretic peptide biomarker levels usually have higher sensitivity than specificity and may be more useful for ruling out than ruling in HF (20). Although lower values of natriuretic peptide biomarkers exclude the presence of HF, and higher values have reasonably high positive predictive value to diagnose HF, clinicians should be aware that elevated plasma levels for both natriuretic peptides have been associated with a wide variety of cardiac and noncardiac causes (Table 2) (38-41).

6.3.3. Biomarkers for Prognosis or Added Risk Stratification: Recommendations

<table>
<thead>
<tr>
<th>Biomarkers: Recommendations for Prognosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>COR</td>
</tr>
<tr>
<td>I</td>
</tr>
<tr>
<td>I</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Higher levels of natriuretic peptide biomarkers on admission are usually associated with greater risk for clinical outcomes, including all-cause and cardiovascular mortality, morbidity, and composite outcomes, across different time intervals in patients with decompensated HF (20, 27, 29, 93-101). Similarly, abnormal levels of circulating cardiac troponin are commonly found in patients with acute decompensated HF, often without obvious...
myocardial ischemia or underlying coronary artery disease (CAD), and this is associated with worse clinical outcomes and higher risk of death (95, 99, 102, 103).

Studies have demonstrated incremental prognostic value of these biomarkers to standard approaches of cardiovascular disease risk assessment (29, 95). However, there were differences in the risk prediction models, assay cutpoints, and lengths of follow-up (29). Furthermore, not all patients may need biomarker measurement for prognostication, especially if they already have advanced HF with established poor prognosis or persistently elevated levels of biomarkers in former settings. Therefore, assays of natriuretic peptide biomarkers for incremental prognostication should not preclude good clinical judgment; an individualized approach to each patient is paramount.

**IIa**

**B-NR**

**During a HF hospitalization, a predischarge natriuretic peptide level can be useful to establish a postdischarge prognosis (93, 96, 104-113).**

See Online Data Supplements A and B.

NEW: Current recommendation reflects new observational studies.

Predischarge natriuretic peptide biomarker levels and the relative change in levels during hospital treatment are strong predictors of the risk of death or hospital readmission for HF (93, 96, 104-113). Several studies have suggested that predischarge natriuretic peptide biomarker levels had higher reclassification and discrimination value than clinical variables in predicting outcomes (96, 106, 108-111). Patients with higher predischarge levels and patients who do not have a decrease in natriuretic peptide biomarker levels during hospitalization have worse outcomes (96, 106, 108-111). Although observational or retrospective studies have suggested that patients with natriuretic peptide biomarker reduction had better outcomes than those without any changes or with a biomarker rise (93, 107, 112, 113), targeting a certain threshold, value, or relative change in these biomarker levels during hospitalization may not be practical or safe for every patient and has not been tested in a prospective large-scale trial. Clinical assessment and adherence to GDMT should be the emphasis, and the prognostic value of a predischarge value or relative changes does not imply the necessity for serial and repeated biomarker measurements during hospitalization.

**IIb**

**B-NR**

**In patients with chronic HF, measurement of other clinically available tests, such as biomarkers of myocardial injury or fibrosis, may be considered for additive risk stratification (27, 95, 98, 99, 103, 114-119).**

See Online Data Supplements A and B.

MODIFIED: 2013 recommendations have been combined into prognosis section, resulting in LOE change from A to B-NR.

Biomarkers of myocardial fibrosis (e.g., soluble ST2 receptor, galectin-3, high-sensitivity cardiac troponin, and others) are predictive of hospitalization and death in patients with HF and also are additive to natriuretic peptide biomarker levels in their prognostic value (117, 119-126). A combination of biomarkers may ultimately prove to be more informative than single biomarkers (127).
Colors correspond to COR in Table 1.
*Other biomarkers of injury or fibrosis include soluble ST2 receptor, galectin-3, and high-sensitivity troponin.
ACC indicates American College of Cardiology; AHA, American Heart Association; ADHF, acute decompensated heart failure; BNP, B-type natriuretic peptide; COR, Class of Recommendation; ED, emergency department; HF, heart failure; NT-proBNP, N-terminal pro-B-type natriuretic peptide; NYHA, New York Heart Association; and pts, patients.

<tr>
<td>I</td>
<td>ACE-I: A</td>
<td>The clinical strategy of inhibition of the renin-angiotensin system with ACE inhibitors <em>(Level of Evidence: A)</em> (128-133), OR ARBs <em>(Level of Evidence: A)</em> (134-137), OR ARNI <em>(Level of Evidence: B-R)</em> (138) in conjunction with evidence-based beta blockers (9, 139, 140), and aldosterone antagonists in selected patients (141, 142), is recommended for patients with chronic HF to reduce morbidity and mortality.</td>
<td>NEW: New clinical trial data prompted clarification and important updates.</td>
</tr>
<tr>
<td></td>
<td>ARB: A</td>
<td>Angiotensin-converting enzyme (ACE) inhibitors reduce morbidity and mortality in heart failure with reduced ejection fraction (HFrEF). Randomized controlled trials (RCTs) clearly establish the benefits of ACE inhibition in patients with mild, moderate, or severe symptoms of HF and in patients with or without coronary artery disease (128-133). ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough but also may contribute to their beneficial effect through vasodilation. Angiotensin receptor blockers (ARBs) were developed with the rationale that angiotensin II production continues in the presence of ACE inhibition, driven through alternative enzyme pathways. ARBs do not inhibit kininase and are associated with a much lower incidence of cough and angioedema than ACE inhibitors; but like ACE inhibitors, ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium. Long-term therapy with ARBs produces hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system and have been shown in RCTs (134-137) to reduce morbidity and mortality, especially in ACE inhibitor–intolerant patients. In ARNI, an ARB is combined with an inhibitor of neprilysin, an enzyme that degrades natriuretic peptides, bradykinin, adrenomedullin, and other vasoactive peptides. In an RCT that compared the first approved ARNI, valsartan/sacubitril, with enalapril in symptomatic patients with HFrEF tolerating an adequate dose of either ACE inhibitor or ARB, the ARNI reduced the composite endpoint of cardiovascular death or HF hospitalization significantly, by 20% (138). The benefit was seen to a similar extent for both death and HF hospitalization and was consistent across subgroups. The use of ARNI is associated with the risk of hypotension and renal insufficiency and may lead to angioedema, as well.</td>

<tr>
<td>----</td>
<td>---------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ACE inhibitors have been shown in large RCTs to reduce morbidity and mortality in patients with HFrEF with mild, moderate, or severe symptoms of HF, with or without coronary artery disease (128-133). Data suggest that there are no differences among available ACE inhibitors in their effects on symptoms or survival (143). ACE inhibitors should be started at low doses and titrated upward to doses shown to reduce the risk of cardiovascular events in clinical trials. ACE inhibitors can produce angioedema and should be given with caution to patients with low systemic blood pressures, renal insufficiency, or elevated serum potassium (&gt;5.0 mEq/L). Angioedema occurs in &lt;1% of patients who take an ACE inhibitor, but it occurs more frequently in blacks and women (144). Patients should not be given ACE inhibitors if they are pregnant or plan to become pregnant. ACE inhibitors also inhibit kininase and increase levels of bradykinin, which can induce cough in up to 20% of patients but also may contribute to beneficial vasodilation. If maximal doses are not tolerated, intermediate doses should be tried; abrupt withdrawal of ACE inhibition can lead to clinical deterioration and should be avoided. Although the use of an ARNI in lieu of an ACE inhibitor for HFrEF has been found to be superior, for those patients for whom ARNI is not appropriate, continued use of an ACE inhibitor for all classes of HFrEF remains strongly advised.</td>

<tr>
<td>I</td>
<td>ARB: A</td>
<td><strong>The use of ARBs to reduce morbidity and mortality is recommended in patients with prior or current symptoms of chronic HFrEF who are intolerant to ACE inhibitors because of cough or angioedema</strong> (134-137, 145, 146).</td>
<td>2013 recommendation repeated for clarity in this section.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ARBs have been shown to reduce mortality and HF hospitalizations in patients with HFrEF in large RCTs (134-137). Long-term therapy with ARBs in patients with HFrEF produces hemodynamic, neurohormonal, and clinical effects consistent with those expected after interference with the renin-angiotensin system (145, 146). Unlike ACE inhibitors, ARBs do not inhibit kininase and are associated with a much lower incidence of cough and angioedema, although kininase inhibition by ACE inhibitors may produce beneficial vasodilatory effects. Patients intolerant to ACE inhibitors because of cough or angioedema should be started on ARBs; patients already tolerating ARBs for other indications may be continued on ARBs if they subsequently develop HF. ARBs should be started at low doses and titrated upward, with an attempt to use doses shown to reduce the risk of cardiovascular events in clinical trials. ARBs should be given with caution to patients with low systemic blood pressure, renal insufficiency, or elevated serum potassium (&gt;5.0 mEq/L). Although ARBs are</td>
<td></td>
</tr>
</tbody>
</table>
alternatives for patients with ACE inhibitor–induced angioedema, caution is advised because some patients have also developed angioedema with ARBs. Head-to-head comparisons of an ARB versus ARNI for HF do not exist. 

For those patients for whom an ACE inhibitor or ARNI is inappropriate, use of an ARB remains advised.

<th><strong>NEW:</strong> New clinical trial data necessitated this recommendation.</th>
</tr>
</thead>
</table>

Benefits of ACE inhibitors with regard to decreasing HF progression, hospitalizations, and mortality rate have been shown consistently for patients across the clinical spectrum, from asymptomatic to severely symptomatic HF. Similar benefits have been shown for ARBs in populations with mild-to-moderate HF who are unable to tolerate ACE inhibitors. In patients with mild-to-moderate HF (characterized by either 1) mildly elevated natriuretic peptide levels, BNP [B-type natriuretic peptide] \(\geq 150\) pg/mL or NT-proBNP [N-terminal pro-B-type natriuretic peptide] \(\geq 600\) pg/mL; or 2) BNP \(\geq 100\) pg/mL or NT-proBNP \(\geq 400\) pg/mL with a prior hospitalization in the preceding 12 months) who were able to tolerate both a target dose of enalapril (10 mg twice daily) and then subsequently an ARNI (valsartan/sacubitril; 200 mg twice daily, with the ARB component equivalent to valsartan 160 mg), hospitalizations and mortality were significantly decreased with the valsartan/sacubitril compound compared with enalapril. The target dose of the ACE inhibitor was consistent with that known to improve outcomes in previous landmark clinical trials (129). This ARNI has been approved for patients with symptomatic HFrEF and is intended to be substituted for ACE inhibitors or ARBs. HF effects and potential off-target effects may be complex with inhibition of the neprilysin enzyme, which has multiple biological targets. Use of an ARNI is associated with hypotension and a low-frequency incidence of angioedema. To facilitate initiation and titration, the approved ARNI is available in 3 doses that include a dose that was not tested in the HF trial; the target dose used in the trial was 97/103 mg twice daily (147). Clinical experience will provide further information about the optimal titration and tolerability of ARNI, particularly with regard to blood pressure, adjustment of concomitant HF medications, and the rare complication of angioedema (14).

**NEW:** Available evidence demonstrates a potential signal of harm for a concomitant use of ACE inhibitors and ARNI.

See Online Data Supplements 1 and 18.
Oral neprilysin inhibitors, used in combination with ACE inhibitors can lead to angioedema and concomitant use is contraindicated and should be avoided. A medication that represented both a neprilysin inhibitor and an ACE inhibitor, omapatrilat, was studied in both hypertension and HF, but its development was terminated because of an unacceptable incidence of angioedema (148, 149) and associated significant morbidity. This adverse effect was thought to occur because both ACE and neprilysin break down bradykinin, which directly or indirectly can cause angioedema (149, 150). An ARNI should not be administered within 36 hours of switching from or to an ACE inhibitor.

**III: Harm**

<table>
<thead>
<tr>
<th>C-EO</th>
<th>ARNI should not be administered to patients with a history of angioedema.</th>
<th>NEW: New clinical trial data.</th>
</tr>
</thead>
</table>

Omapatrilat, a neprilysin inhibitor (as well as an ACE inhibitor and aminopeptidase P inhibitor), was associated with a higher frequency of angioedema than that seen with enalapril in an RCT of patients with HF\(r\)EF (148). In a very large RCT of hypertensive patients, omapatrilat was associated with a 3-fold increased risk of angioedema as compared with enalapril (149). Blacks and smokers were particularly at risk. The high incidence of angioedema ultimately led to cessation of the clinical development of omapatrilat (151, 152). In light of these observations, angioedema was an exclusion criterion in the first large trial assessing ARNI therapy in patients with hypertension (153) and then in the large trial that demonstrated clinical benefit of ARNI therapy in HF\(r\)EF (138). ARNI therapy should not be administered in patients with a history of angioedema because of the concern that it will increase the risk of a recurrence of angioedema.

**7.3.2.11. Ivabradine: Recommendation**

<table>
<thead>
<tr>
<th>recommendation for ivabradine</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Recommendation</strong></td>
</tr>
<tr>
<td><strong>COR</strong></td>
</tr>
</tbody>
</table>

**IIa**

| B-R | Ivabradine can be beneficial to reduce HF hospitalization for patients with symptomatic (NYHA class II-III) stable chronic HF\(r\)EF (LVEF ≤35%) who are receiving GDEM*, including a beta blocker at maximum tolerated dose, and who are in sinus rhythm with a heart rate of 70 bpm or greater at rest (154-157). |

Ivabradine is a new therapeutic agent that selectively inhibits the I\(_f\) current in the sinoatrial node, providing heart rate reduction. One RCT demonstrated the efficacy of ivabradine in reducing the composite endpoint of cardiovascular death or HF hospitalization (155). The benefit of ivabradine was driven by a reduction in HF hospitalization. The study included patients with HF\(r\)EF (NYHA class II-IV, albeit with only a modest representation of NYHA class IV HF) and left ventricular ejection fraction (LVEF) ≤35%, in sinus rhythm with a resting heart rate of ≥70 beats per minute. Patients enrolled included a small number with paroxysmal atrial fibrillation (<40% of the time) but otherwise in...
sinus rhythm and a small number experiencing ventricular pacing but with a predominant sinus rhythm. Those with a myocardial infarction within the preceding 2 months were excluded. Patients enrolled had been hospitalized for HF in the preceding 12 months and were on stable GDEM* for 4 weeks before initiation of ivabradine therapy. The target of ivabradine is heart rate slowing (the presumed benefit of action), but only 25% of patients studied were on optimal doses of beta-blocker therapy (9, 139, 140, 155). Given the well-proven mortality benefits of beta-blocker therapy, it is important to initiate and up titrate these agents to target doses, as tolerated, before assessing the resting heart rate for consideration of ivabradine initiation (155).

*In other parts of the document, the term “GDMT” has been used to denote guideline-directed management and therapy. In this recommendation, however, the term “GDEM” has been used to denote this same concept in order to reflect the original wording of the recommendation that initially appeared in the “2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure: An Update of the 2013 ACCF/AHA Guideline for the Management of Heart Failure” (10).
Figure 2. Treatment of HFrEF Stage C and D

Step 1: Establish Dx of HFrEF; assess volume; initiate GDMT

Step 2: Consider the following patient scenarios

- NYHA class II–IV, provided est. CrCl >30 mL/min & K+ <5.0 mEq/L
  - Aldosterone antagonist (COR I)

- NYHA class II–III HF
  - Adequate BP on ACEI or ARB*: No C/I to ARB or sacubitril
  - Discontinue ACEI or ARB; initiate ARNI** (COR I)

Step 3: Implement indicated GDMT. Choices are not mutually exclusive, and no order is inferred

- NYHA class III–IV, in black patients
  - Hydral-Nitrates†‡ (COR I)

- NYHA class II–III, LVEF ≤35%, (caveat: >1 y survival, >40 d post MI)
  - ICD‡ (COR I)

- NYHA class II–IV, LVEF ≤35%, NSR & QRS ≥150 ms with LBBB pattern
  - CRT or CRT-D‡ (COR I)

- NYHA class II–III, NSR, heart rate ≥70 bpm on maximally tolerated dose beta blocker
  - Ivabradine (COR Iia)

Step 4: Reassess symptoms

- NYHA class III–IV (Stage D)
  - Refractory NYHA class III–IV

Step 5: Consider additional therapy

- Palliative care‡ (COR I)
- Transplant‡ (COR I)
- LVAD‡ (COR IIa)

Continue GDMT with serial reassessment & optimized dosing/adherence

Colors correspond to COR in Table 1. For all medical therapies, dosing should be optimized and serial assessment exercised.

*See text for important treatment directions.
†Hydral-Nitrates green box: The combination of ISDN/HYD with ARNI has not been robustly tested. BP response should be carefully monitored.
‡See 2013 HF guideline (9).
§Participation in investigational studies is also appropriate for stage C, NYHA class II and III HF.

ACEI indicates angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor-blocker; ARNI, angiotensin receptor-neprilysin inhibitor; BP, blood pressure; bpm, beats per minute; C/I, contraindication; COR, Class of Recommendation; CrCl, creatinine clearance; CRT-D, cardiac resynchronization therapy–device; Dx, diagnosis; GDMT, guideline-directed management and therapy; HF, heart failure; HFrEF, heart failure with reduced ejection fraction; ICD, implantable cardioverter-defibrillator; ISDN/HYD, isosorbide dinitrate-hydral-nitrates; K+, potassium; LBBB, left bundle-branch block; LVAD, left ventricular assist device; LVEF, left ventricular ejection fraction; MI, myocardial infarction; NSR, normal sinus rhythm; and NYHA, New York Heart Association.

<td>In appropriately selected patients with HFpEF (with EF ≥45%, elevated BNP levels or HF admission within 1 year, estimated glomerular filtration rate &gt;30 ml/min, creatinine &lt;2.5 mg/dl, potassium &lt;5.0 mEq/L), aldosterone receptor antagonists might be considered to decrease hospitalizations (83, 166, 167).</td>
<td>NEW: Current recommendation reflects new RCT data.</td>
</tr>
</tbody>
</table>

Mechanistic studies have suggested that mineralocorticoid receptor antagonists can improve measures of diastolic function in patients with HFpEF, possibly by a similar effect on remodeling (83, 168).

The TOPCAT (Treatment of Preserved Cardiac Function Heart Failure With an Aldosterone Antagonist) trial (166) investigated the effects of spironolactone on a combined endpoint of death, aborted cardiac death, and HF hospitalization in patients with HFpEF. A small reduction (HR=0.89) in this composite endpoint did not reach statistical significance, although HF hospitalization was reduced (HR=0.83); known side effects of hyperkalemia and rising creatinine were seen more commonly in the treatment group (166). An unusual amount of regional variation was seen in this trial, prompting a post-hoc analysis (167) that showed that rates of the primary endpoint were 4-fold lower in Russia/Georgia than in North America and South America (the Americas). Rates in the Americas were comparable to those in other HFpEF trials (169, 170). The post-hoc analysis showed efficacy in the Americas (HR=0.83) but not in Russia/Georgia (HR=1.10). Moreover, a sample of the Russia/Georgia population, despite having been in the active treatment arm, had nondetectable levels of...
the metabolite of spironolactone. These post-hoc analyses have significant limitations, but they suggest that in appropriately selected patients with symptomatic HFpEF (with ejection fraction [EF] ≥45%, elevated BNP level or HF admission within 1 year, estimated glomerular filtration rate >30 mL/min creatinine <2.5 mg/dL, and potassium <5.0 mEq/L), particularly in those with elevated BNP levels, use of spironolactone might be considered with close monitoring of potassium and renal function. Confirmatory studies are required.

With regard to the use of mineralocorticoid receptor antagonists, creatinine should be <2.5 mg/dL in men or <2.0 mg/dL in women (or estimated glomerular filtration rate >30 mL/min) and potassium should be <5.0 mEq/L. Careful monitoring of potassium, renal function, and diuretic dosing represents best practices at initiation and during follow-up thereafter to minimize risk of hyperkalemia and worsening renal function.

| IIb | B | The use of ARBs might be considered to decrease hospitalizations for patients with HFpEF (169). | 2013 recommendation remains current. |
| III: No Benefit | B-R | Routine use of nitrates or phosphodiesterase-5 inhibitors to increase activity or QoL in patients with HFpEF is ineffective (171, 172). | NEW: Current recommendation reflects new data from RCTs. |
| | | See Online Data Supplement C. | |

Nitrate therapy can reduce pulmonary congestion and improve exercise tolerance in patients with HFpEF. However, the NEAT-HFpEF (Nitrate’s Effect on Activity Tolerance in Heart Failure With Preserved Ejection Fraction) trial (171) randomized 110 patients with EF ≥50% on stable HF therapy, not including nitrates, and with activity limited by dyspnea, fatigue, or chest pain, to either isosorbide mononitrate or placebo and found no beneficial effects on activity levels, QoL, exercise tolerance, or NT-proBNP levels. On the basis of this trial, routine use of nitrates in patients with HFpEF is not recommended. This recommendation does not apply to patients with HFpEF and symptomatic CAD for whom nitrates may provide symptomatic relief.

Phosphodiesterase-5 inhibition augments the nitric oxide system by upregulating cGMP activity. The RELAX (Phosphodiesterase-5 Inhibition to Improve Clinical Status and Exercise Capacity in Heart Failure with Preserved Ejection Fraction) trial (172) randomized 216 patients with EF ≥50% on stable HF therapy and with reduced exercise tolerance (peak observed VO₂ <60% of predicted) to phosphodiesterase-5 inhibition with sildenafil or placebo. This study did not show improvement in oxygen consumption or exercise tolerance.

| III: No Benefit | C | Routine use of nutritional supplements is not recommended for patients with HFpEF. | 2013 recommendation remains current. |

9. Important Comorbidities in HF

9.2. Anemia: Recommendations

<td>B-R</td>
<td>In patients with NYHA class II and III HF and iron deficiency (ferritin &lt;100 ng/mL or 100 to 300 ng/mL if transferrin saturation is &lt;20%), intravenous iron replacement might be reasonable to improve functional status and QoL(173, 174).</td>
<td>NEW: New evidence consistent with therapeutic benefit.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See Online Data Supplement D.</td>
<td></td>
</tr>
</tbody>
</table>

Routine baseline assessment of all patients with HF includes an evaluation for anemia in addition to other baseline laboratory measurements. Anemia is independently associated with HF disease severity, and iron
deficiency appears to be uniquely associated with reduced exercise capacity. When iron deficiency is diagnosed and after full evaluation for cause, intravenous repletion of iron, especially in the setting of concomitant hepcidin deficiency in HF, may improve exercise capacity and QoL. Studies examining correction of iron deficiency in HF have demonstrated improvement in surrogate endpoints, such as QoL, NT-proBNP, and LVEF; however, controlled trials have been underpowered to detect reductions in hard clinical endpoints. The FAIR-HF (Ferric Carboxymaltose Assessment in Patients With Iron Deficiency and Chronic Heart Failure) trial (173) demonstrated improvements in NYHA class and functional capacity over a short-term exposure. The CONFIRM-HF (Ferric Carboxymaltose Evaluation on Performance in Patients With Iron Deficiency in Combination with Chronic Heart Failure) trial (174) included a larger cohort of patients (n=304) and demonstrated improvements in 6-minute walk test. A meta-analysis of 5 prospective controlled studies (631 patients) evaluated the effect of intravenous iron on deaths, hospitalizations, and other events in patients with HF and iron deficiency (175). Patients receiving intravenous iron experienced limited but statistically significant improvements in functional capacity and LVEF but no reduction in mortality rate. The FAIR-HF 2 trial is underway to further address the potential benefit of intravenous iron in HF associated with iron deficiency. Therefore, a strong recommendation for intravenous iron repletion must await the results of an appropriately powered trial on morbidity and mortality. There is an uncertain evidence base for oral iron repletion in the setting of anemia associated with HF.

| III: No Benefit | B-R | In patients with HF and anemia, erythropoietin-stimulating agents should not be used to improve morbidity and mortality (176). | NEW: Current recommendation reflects new evidence demonstrating absence of therapeutic benefit. |
| See Online Data Supplement D. | |

Small studies evaluating the treatment of anemia in patients with HF have suggested a trend toward improvement in functional capacity and reduction in hospitalization with the use of erythropoietin-stimulating agents (177-182), but results have varied (183) and have been limited because of sample size. Although a meta-analysis of 11 RCTs (n=794) comparing erythropoietin-stimulating agents to control in patients with HF demonstrated significant improvements in 6-minute walk, exercise duration, peak VO₂, NYHA functional status, EF, BNP, HF-related hospitalizations, and QoL (184), in the STAMINA-HeFT (Study of Anemia in Heart Failure) trial (183), darbepoetin alfa was not associated with significant clinical benefits. In the largest RCT to date (n=2,278), correction of anemia with darbepoetin alfa did not result in benefit and resulted in a significant increase in the risk of thromboembolic events and a nonsignificant increase in fatal and nonfatal strokes, supporting findings from other trials (176, 185-188). In summary, the strongest evidence on erythropoietin-stimulating agent therapy in HF suggests lack of benefit and increased adverse events. Therefore, erythropoietin-stimulating agent therapy cannot be recommended in patients with HF and anemia.

### 9.5. Hypertension (New Section)

#### 9.5.1. Treating Hypertension to Reduce the Incidence of HF: Recommendation

<table>
<thead>
<tr>
<th>Recommendation for Prevention</th>
<th>COR</th>
<th>LOE</th>
<th>Recommendations</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>B-R</td>
<td></td>
<td>In patients at increased risk, stage A HF, the optimal blood pressure in those with hypertension should be</td>
<td>NEW: Recommendation reflects new RCT data.</td>
</tr>
</tbody>
</table>
A large RCT demonstrated that in those with increased cardiovascular risk (defined as age >75 years, established vascular disease, chronic renal disease, or a Framingham Risk Score >15%), control of blood pressure to a goal systolic pressure of <120 mm Hg, as determined by blood pressure assessment as per research protocol, was associated with a significant reduction in the incidence of HF (191) and an overall decrease in cardiovascular death. Blood pressure measurements as generally taken in the office setting are typically 5 to 10 mm Hg higher than research measurements; thus, the goal of <130/80 mm Hg is an approximation of the target blood pressure in conventional practice. Targeting a significant reduction in systolic blood pressure in those at increased risk for cardiovascular disease is a novel strategy to prevent HF.

9.5.2. Treating Hypertension in Stage C HFrEF: Recommendation

<table>
<thead>
<tr>
<th>Recommendation for Hypertension in Stage C HFrEF</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patients with HFrEF and hypertension should be prescribed GDMT titrated to attain systolic blood pressure less than 130 mm Hg (191).</td>
<td>NEW: Recommendation has been adapted from recent clinical trial data but not specifically tested per se in a randomized trial of patients with HF.</td>
</tr>
</tbody>
</table>

Clinical trials evaluating goal blood pressure reduction and optimal blood pressure–lowering agents in the setting of HFrEF and concomitant hypertension have not been done. However, it is apparent that in those patients at higher risk, blood pressure lowering is associated with fewer adverse cardiovascular events. GDMT for HFrEF with agents known to lower blood pressure should consider a goal blood pressure reduction consistent with a threshold now associated with improved clinical outcomes but not yet proven by RCTs in a population with HF.

9.5.3. Treating Hypertension in Stage C HFpEF: Recommendation

<table>
<thead>
<tr>
<th>Recommendation for Hypertension in Stage C HFpEF</th>
<th>Comment/Rationale</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patients with HFpEF and persistent hypertension after management of volume overload should be prescribed GDMT titrated to attain systolic blood pressure less than 130 mm Hg (167, 169, 170, 194-199).</td>
<td>NEW: New target goal blood pressure based on updated interpretation of recent clinical trial data.</td>
</tr>
</tbody>
</table>

The use of nitrates in the setting of HFpEF is associated with a signal of harm and, in most situations, should be avoided. For many common antihypertensive agents, including alpha blockers, beta blockers, and calcium channel blockers, there are limited data to guide the choice of antihypertensive therapy in the setting of HFpEF (172). Nevertheless, RAAS inhibition with ACE inhibitor, ARB (especially mineralocorticoid receptor antagonists), and possibly ARNI would represent the preferred choice. A shared decision-making discussion with the patient influenced by physician judgment should drive the ultimate choice of antihypertensive agents.
9.6. Sleep Disordered Breathing: Recommendations

(Moved from Section 7.3.1.4, Treatment of Sleep Disorders in the 2013 HF guideline.)

<table>
<thead>
<tr>
<th>Recommendations for Treatment of Sleep Disorders</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>COR</strong></td>
</tr>
<tr>
<td>IIa</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Sleep disorders are common in patients with HF. A study of adults with chronic HF treated with evidence-based therapies found that 61% had either central or obstructive sleep apnea (202). It is clinically important to distinguish obstructive sleep apnea from central sleep apnea, given the different responses to treatment. Adaptive servo-ventilation for central sleep apnea is associated with harm (203). Continuous positive airway pressure (CPAP) for obstructive sleep apnea improves sleep quality, reduces the apnea-hypopnea index, and improves nocturnal oxygenation (200, 201).

**IIb**

| **B-R** | In patients with cardiovascular disease and obstructive sleep apnea, CPAP may be reasonable to improve sleep quality and daytime sleepiness (204). | NEW: New data demonstrate the limited scope of benefit expected from CPAP for obstructive sleep apnea. |
|         | See Online Data Supplement G. | |

In patients with sleep apnea, a trial evaluated the impact of CPAP with usual therapy versus usual therapy alone on subsequent cardiovascular events, including HF (204). In this RCT of >2,700 patients, there was no evidence of benefit on cardiovascular events at a mean follow-up of 3.7 years for CPAP plus usual care compared with usual care alone. Improvements in sleep quality were noteworthy and represented the primary indication for initiating CPAP treatment (204). However, in patients with atrial fibrillation (AF) (a frequent comorbidity noted with HF), the use of CPAP for obstructive sleep apnea was helpful. In a trial of 10,132 patients with AF and obstructive sleep apnea, patients on CPAP treatment were less likely to progress to more permanent forms of AF than were patients without CPAP (205).

**III: Harm**

| **B-R** | In patients with NYHA class II–IV HFrEF and central sleep apnea, adaptive servo-ventilation causes harm (203). | NEW: New data demonstrate a signal of harm when adaptive servo-ventilation is used for central sleep apnea. |
|         | See Online Data Supplement G. | |

Mortality rate (all cause and cardiovascular) was higher with adaptive servo-ventilation plus GDMT than with GDMT alone in a single RCT to test the addition of adaptive servo-ventilation (≥5 hours/night, 7 days/week) to GDMT in patients with HFrEF and central sleep apnea (203). A similar risk has been seen in another trial, and a third trial of adaptive servo-ventilation in central sleep apnea and HF was aborted because of ethical concerns. The weight of evidence does not support the use of adaptive servo-ventilation for central sleep apnea in HFrEF.

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of $5,000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACC/AHA, a person has a relevant relationship IF: a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.

†Significant relationship.

This table represents the relationships of reviewers with industry and other entities that were disclosed at the time of peer review, including those not deemed to be relevant to this document. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of \( \geq 5\% \) of the voting stock or share of the business entity, or ownership of \( \geq 5,000 \) of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the person’s gross income for the previous year. A relationship is considered to be modest if it is less than significant under the preceding definition. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review.

American College of Physicians did not provide a peer reviewer for this document.

*Significant relationship.
†No financial benefit.
AAFP indicates American Academy of Family Physicians; ACC, American College of Cardiology; ACCF, American College of Cardiology Foundation; AHA, American Heart Association; ASA, American Stroke Association; CHEST, American College of Chest Physicians; CIHR, Canadian Institutes of Health Research; DSMB, data safety monitoring board; FH, familial hypercholesterolemia; GWTG, Get With The Guidelines; HFSA, Heart Failure Society of America; ISHLT, International Society for Heart and Lung Transplantation; NIH, National Institutes of Health; NHLBI, National Heart, Lung, and Blood Institute; NQF, National Quality Forum; PCORI, Patient-Centered Outcomes Research Institute; SCAI, Society for Cardiac Angiography and Interventions; SUNY, State University of New York; UT, University of Texas; and VA, Veterans Affairs.
Appendix 3. Abbreviations

ACE = angiotensin-converting enzyme
ARB = angiotensin-receptor blocker
ARNI = angiotensin receptor–neprilysin inhibitor
BNP = B-type natriuretic peptide
BP = blood pressure
COR = Class of Recommendation
CPAP = continuous positive airway pressure
EF = ejection fraction
GDMT = guideline-directed management and therapy
HFpEF = heart failure with preserved ejection fraction
HFrEF = heart failure with reduced ejection fraction
LOE = Level of Evidence
LVEF = left ventricular ejection fraction
NT-proBNP = N-terminal pro-B-type natriuretic peptide
QoL = quality of life
RCT = randomized controlled trial

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$5,000 of the fair market value of the business entity, or if funds received by the person from the business entity exceed 5% of the

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
person’s gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACC/AHA, a person has a relevant relationship IF: a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or c) the person or a member of the person’s household has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.
†Significant relationship.

ACC indicates American College of Cardiology; AHA, American Heart Association; DCRI, Duke Clinical Research Institute; DSMB, data safety monitoring board; HFSA, Heart Failure Society of America; INTERMACS, Interagency Registry for Mechanically Assisted Circulatory Support; PARENT, Pulmonary Artery Pressure Reduction With Entresto; UCLA, University of California, Los Angeles; and VA, Veterans Affairs.
2017 Heart Failure Focused Update Data Supplement

| PONTIAC Huelsmann et al. 2013 (1) 23810874 | **Aim:** To assess the effectiveness of neurohumoral therapy for the prevention of cardiac events in pts with type 2 DM with increased biomarker NT-proBNP | **Inclusion criteria:** Pts with type 2 DM, age ≥18 y, elevated NT-proBNP (≥125 pg/mL) | **Intervention:** Individualized up-titration of RAS antagonists and beta blockers in addition to diabetes treatment (150), treated at cardiology clinic | **1° endpoint:** Hospitalization or death due to cardiac disease following 24 mo  
Results: Significant reduction of 1° endpoint in intervention group (HR: 0.351; 95% CI: 0.127–0.975; p=0.044)  
1° Safety endpoint:  
- BP was significantly reduced in both intervention and control (p<0.05); heart rate was only reduced in the intensified group (p=0.004)  
- All-cause hospitalizations, HF hospitalizations and unplanned CV hospitalizations or death (p<0.05 reduction)  
- Study limitations: Absence of pt randomization for treatment, pt population mainly Caucasian, statistical analysis done without adjustment of co-variates  
- Pts treated with a RAS antagonist/beta-blocker and the dosage reached higher in intensified group (p<0.0001)  
- No difference in NT-proBNP levels |  |
| STOP-HF Ledwidge et al. 2013 (2) 23821090 | **Aim:** To establish efficacy of BNP screening and collaborative care in at-risk population in reducing newly | **Inclusion criteria:** Pts ≥40 y, and history of HTN (on meds ≥1 mo), hypercholesterolemia, obesity, vascular disease including | **Intervention:** BNP screening at BL and annually and protocol referral for BNP ≥50 pg/mL for echocardiography and collaborative care (697) | **1° endpoint:** LV dysfunction (systolic: LVEF <50% or diastolic: E/E’ ratio >15) with or without newly diagnosed HF (with symptoms of HF requiring admission to  
Emergency hospitalizations for major MACE [40 vs. 22 (0.60 OR; 95% CI: .45-0.81; p=.002)])  
CV investigations more likely to be done in the intervention group with BNP levels ≥50 pg/mL

### Aim:
To assess the effects of NP-guided treatment of chronic HF on outcomes

### Study type:
Meta-analysis

### Size:
14 studies, 3,004 pts

### Exclusion criteria:
N/A

### Inclusion criteria:
Prospective RCTs with adult HF pts comparing the effects of BNP or NT-proBNP-guided therapy with clinically guided therapy

### Intervention:
BNP or NT-proBNP-guided therapy (1,503)

### Comparator:
Clinically guided therapy (1,501)

### 1° endpoints:
- All-cause mortality, HF hospitalization, all-cause hospitalization, safety (adverse events)

### Results:
- All-cause mortality was significantly reduced by NP-guided treatment [HR: 0.62 (0.45–0.86); p=0.004]
- HF hospitalizations were reduced in the NP-guided group, compared with clinically guided pts [HR: 0.80 (0.67–0.94); p=0.009] as were CV admissions [HR: 0.82 (0.67–0.99); p=0.048]
- Each of the included RCTs was relatively small and 2 trials did not

### Troughton RW et al. 2014

### Aim:
To assess the effects of NP-guided treatment of chronic HF on outcomes

### Study type:
Meta-analysis

### Size:
9 reviews

### Exclusion criteria:
N/A

### Inclusion criteria:
4 SRs assessed HF hospitalization and “consistently” found a significant reduction with NP-guided therapy

### Intervention:
BNP or NT-proBNP-guided therapy

### Comparator:
Clinically guided therapy

### Results:
- Compared with clinical group, BNP-guided treatment significantly decreased the risk of HF-related hospitalization (RR: 0.79; 95% CI: 0.63–0.98; p=0.03), although did not significantly affect the risk of all-cause mortality (RR: 0.94, 95% CI: 0.81–1.08, p=0.39) or all-cause hospitalization (RR: 0.97; 95% CI: 0.89–1.07; p=0.56).

### 1° Safety endpoint:
- NP-guided therapy was not associated with increased risk for serious adverse events.

### Inclusion criteria

- Prospective RCTs of pts with chronic HF randomized pts to a strategy of titrating medical therapy based on the level of a circulating biomarker compared to a parallel control group, reporting all-cause mortality

### Intervention: BNP-guided therapy

### Comparator: Clinically guided therapy

### Results: Significant mortality advantage for biomarker-guided therapy (HR: 0.69, 95% CI: 0.55–0.86) compared to control

### In pts <75 y, all-cause mortality was significantly lower in the BNP-guided group (RR: 0.52; 95% CI: 0.33–0.82; p=0.005).

### No reduction in mortality with BNP-guided therapy in pts ≥75 y (RR: 0.94; 95% CI: 0.71–1.25; p=0.70).

### All-cause hospitalization and survival free of any hospitalization was not significantly different between groups (RR: 0.82; 95% CI: 0.64–1.05; p=0.12 and RR: 1.07; 95% CI: 0.85–1.34; p=0.58, respectively).

### Additional % pts achieving target doses of ACE-inhibitors and beta blockers 21% and 22% in the BNP group and 11.7% and 12.5% in the control group, respectively.

### Troughton et al. 2000

| **Aim:** | To assess the effects of NT-proBNP-guided treatment of chronic HF on outcomes |
| **Study type:** | RCT |
| **Size:** | 69 pts |

#### Inclusion criteria:
- Ambulatory pts with LVEF <40% and symptomatic HF (NYHA II-IV)

#### Exclusion criteria:
Pts with unknown LVEF

#### Follow up:
Minimum 6 mo (median 9.5 mo)

#### Intervention:
(NT-pro)BNP-guided therapy with a target of NT-proBNP level <200 pmol

#### Comparator: Standardized clinical assessment (clinical group)

#### 1° endpoints:
- Death, CV hospitalization and outpatient HF event

#### Results:
- Fewer CV events (death, hospital, or HF decompensation) in the NT-proBNP group than in the clinical group (19 vs. 54; p=0.02)
- At 6 mo, 27% of pts in the BNP group and 53% in the clinical group had experienced a first CV event (p=0.034).
- Changes in LVEF, QoL, renal function, and adverse events were similar in both groups.
- N-BNP-guided treatment of HF reduced total CV events, and delayed time to first event compared with intensive clinically guided treatment.
- NP was reduced significantly and NP guidance changed therapy

### STARS-BNP

| **Aim:** | To evaluate the prognostic impact of a therapeutic strategy using plasma BNP |
| **Study type:** | RCT |
| **Size:** | 220 pts |

#### Inclusion criteria:
- Ambulatory NYHA class II to III pts considered optimally treated

#### Exclusion criteria:
N/A

#### Follow up:
median 15 mo

#### Intervention:
BNP-guided therapy Target: BNP <100 pg/mL

#### Comparator: Medical treatment according to either current guidelines (clinical group)

#### 1° endpoint
- HF-related death or hospital stay for HF

#### Results:
- Mean dosages of ACE inhibitors and beta blockers significantly higher in the BNP group (p<0.05),
- BNP-guided strategy reduced the risk of HF related death or hospital stay for HF (24% vs. 52%, p<0.001), mainly obtained through an increase in ACE inhibitor and beta blocker dosages.
- NP guidance changed therapy
- Unknown whether BNP-guided therapy resulted in reduction in BNP levels

### TIME-CHF

| **Aim:** | To compare 18-mo outcomes of N-terminal BNP-guided vs. symptom guided HF therapy |
| **Study type:** | |
| **Size:** | |

#### Inclusion criteria:
- Ambulatory HF pts 60 y with systolic HF (LVEF ≤45%), NYHA class of II or greater, prior HF hospitalization within

#### Intervention:
Uptitration of guideline-based treatments to BNP level of ≤2 times of UL (BNP-guided therapy)

#### Targets:
- N-terminal BNP and

#### 1° endpoints:
- 18 mo survival free of all-cause hospitalizations

#### Results:
- Survival free of hospitalization for HF was higher among those in the N-terminal BNP-guided group (72% vs. 62%, respectively; HR: 0.68 [95% CI: 0.50–0.92]; p=0.01).
- N-terminal BNP-guided therapy

---

### BATTLESCARRED

**Laichbury et al. 2009**

**Aim:** to compare the effects of NT-proBNP-guided therapy with those of intensive clinical management and usual care

**Study Type:** RCT (Australia hospitals)

| Study type: | RCT |
| Size: | 364 pts |
| Inclusion criteria: | Pts admitted to a single hospital with HF, NT-proBNP >50 pmoL/l or 400 pg/mL (included HFrEF) |
| Intervention: | Outpatient post d/c therapy guided by NT-proBNP levels |
| Comparator: | Therapy guided by intensive clinical management, or according to usual care |
| 1° endpoints: | Mortality |
| Results: | 1-y mortality was less in both the hormone (9.1%) and clinically-guided (9.1%) groups compared with usual care (18.9%; p=0.03) |

• NT-ProBNP levels were not different between groups: Pt management group had the highest proportion of RAAS inhibition triple-therapy

• Death rate was similar between the pt management (22%) and multidisciplinary care groups (22%), but was lower compared with the usual care group (39%; vs. pt management: p<0.02; vs. multidisciplinary care: p<0.02)

### Berger et al. 2010

**Aim:** To investigate whether the addition of NT-proBNP-guided, intensive pt management to multidisciplinary care improves outcome in pts following hospitalization due to HF

**Study Type:** RCT

| Study type: | RCT |
| Size: | 499 pts |
| Inclusion criteria: | 1 y, and N-terminal BNP level of ≥2 times the upper limit of normal. |
| NT-proBNP <400 pg/mL if age <75 y, NT-proBNP <800 pg/mL if 75 y |
| Comparator: | Up titration of guideline-based treatments to reduce symptoms to NYHA class of II or less (symptom guided therapy) |
| symptom-guided therapy resulted in similar rates of survival free of all-cause hospitalizations (41% vs. 40%, respectively; HR: 0.91 [95% CI: 0.72–1.14]; p=0.39) |
| • BNP guidance changed therapy (higher doses of ACE inhibitors, ARB, Beta blockers and higher use of spironolactone) |
| • NT-ProBNP levels were not different between groups |

• QoL improvements were similar in both the N-terminal BNP-guided and symptom guided strategies
| Study Type: | RCT (8 Viennese hospitals) |
| Study Type: | RCT |
| Size: | 278 pts |
| Size: | 345 pts |

**Study Type:** RCT (8 Viennese hospitals)

**Size:** 278 pts

**Inclusion criteria:** Specialist-therapeutic recommendations and home care by a HF nurse

- Usual care

- NT-ProBNP levels were lowered in guided pt management arm

- In the BM (37%) than in the multidisciplinary care group (50%; p<0.05) and in the multidisciplinary care than in the usual care group (65%; p=0.04)

**Intervention:** After discharge discontinue outpatient management guided by an individually set NT-proBNP (n=174) defined by the lowest level at discharge or 2 wk thereafter.

**Comparators:** Clinically-guided outpatient management (n=171)

**1º endpoints:** Number of d alive outside the hospital after index

**Results:** Management guided by NT-proBNP target did not significantly improve the 1º endpoint p=0.49)

- In the NT-proBNP-guided group mortality was lower, as 46 pts died (26.5%) vs. 57 (33.3%) in the clinically guided group, but this was not statistically significant (p=0.21)

- Individualized NT-proBNP target increased the use of HF medication (p=0.006)

**Aim:** To assess whether management by an individualized NT-proBNP target would lead to improved outcome compared with HF management guided by clinical assessment alone

**Study Type:** RCT

**Size:** 345 pts

**Inclusion criteria:** Hospitalized HF pts with for decompensated, symptomatic HF with NT-proBNP levels >1,700 pg/mL at admission (included HFpEF)

**Intervention:** After discharge discontinue outpatient management guided by an individually set NT-proBNP (n=174) defined by the lowest level at discharge or 2 wk thereafter.

**Comparators:** Clinically-guided outpatient management (n=171)

**1º endpoints:** Number of d alive outside the hospital after index

**Results:** Management guided by NT-proBNP target did not significantly improve the 1º endpoint p=0.49)

- In the NT-proBNP-guided group mortality was lower, as 46 pts died (26.5%) vs. 57 (33.3%) in the clinically guided group, but this was not statistically significant (p=0.21)

- Individualized NT-proBNP target increased the use of HF medication (p=0.006)

**Aim:** To investigate if NT-proBNP-guided therapy in HF pts in 1º care would improve clinical outcomes over and above treatment according to guidelines

**Study Type:** RCT (Sweden 1º care centers)

**Inclusion criteria:** Ambulatory HF pts NYHA class II-IV, LVEF <50% and NT-proBNP levels males >800, females >1,000 ng/

**Intervention:** Structured treatment of HF according to guidelines with or without NT-proBNP monitoring

- Target: At least a 50% reduction from BL NT-proBNP

**1º endpoints:** Composite endpoint of d alive, d out of hospital and symptom score

**Results:** There were no differences between the groups concerning either the 1º endpoint (p=0.28) or its components (CV death, p=0.93; CV hospitalization, p=0.88; or symptom score, p=0.28

- Treatment doses of beta blockers and RAS blockers were markedly increased towards target doses a similar degree in both groups

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
**STARBRITE Trial**  
Shah et al. 2011 (20)  
**Aim:** Whether outpatient diuretic management guided by BNP and clinical assessment better compared with clinical assessment alone  
**Study Type:** Multicenter (3) RCT  
**Size:** 130  
**Inclusion criteria:** Hospitalized HF pts with LEVF ≤35%  
**Exclusion criteria:** Serum creatinine >3.5 mg/dL and ACS  
**Intervention:** Outpatient post discharge BNP and clinical assessment guided therapy  
**Comparator:** Clinical assessment alone.  
**1° endpoints:** Composite endpoint of d alive and d out of hospital,  
**Results:** No significant difference HR: 0.72; 95% CI: 0.41–1.27; p=0.25  
- Change in serum creatinine, or change in SBP not different  
- BNP strategy pts received significantly more ACE inhibitors, beta blockers

**PROTECT Study**  
Gaggin et al. 2012 (21)  
**Aim:** Whether elders benefit from NP-guided HF care  
**Study Type:** Single center RCT  
**Size:** 151  
**Inclusion criteria:** Chronic HF pts with LV systolic dysfunction  
**Intervention:** Management guided by NT-proBNP with a goal to lower NT-proBNP ≤1000 pg/mL over 10 mo  
**Comparator:** Standard of care  
**1° endpoints:** Total CV events in 2 age categories 75 and ≥75 y  
**Results:** Pts ≥75 y with NT-proBNP management had lowest rate of CV events (1.76 events per pt with standard of care vs. 0.71 events per pt with NT-proBNP guide, p=0.03)  
- Improvement in QoL, LVEF, and indices of LV volume with guided approach  
- NP guidance changed therapy: greater use of aldosterone antagonists and lesser use of loop diuretics in the guided therapy group (no difference in ACE inhibitors or beta blockers)

**UPSTEP-study**  
Karlstrom et al. 2011 (22)  
**Aim:** To determine whether BNP-guided HF treatment improves morbidity and/or mortality  
**Inclusion criteria:** Ambulatory HF NYHA II-IV, LVEF <40% and elevated BNP levels  
**Intervention:** BNP-guided (BNP) with a goal <150 or 300 ng/L for elderly  
**Comparator:** Conventional (CTR) HF treatment  
**1° endpoints:** Combined death and worsening/hosp for HF  
**Results:** No significant differences 1° outcome (p=0.18)  
- No differences for d out of hospital, and younger vs. elderly.  
- Subgroup analysis: improved survival (p<0.0001 for the 1° outcome) among responders with >30% decrease in BL BNP value vs. nonresponders.
## Study Type:
- Multicenter RCT-probe design

### Size:
- 279

### Aim:
To validate and characterize the use of BNP in the diagnosis of HF in pts with dyspnea

### Study type:
- Prospective, blinded, diagnostic accuracy study

### Size:
- 1,856

### Inclusion criteria:
- Pts who came to the emergency department with acute dyspnea
- Age <18 y and those whose dyspnea was clearly not secondary to HF (i.e., those with trauma or cardiac tamponade), acute myocardial infarction, unstable angina, or renal failure

### Exclusion criteria:
- Pts with trauma or cardiac tamponade, acute myocardial infarction, unstable angina, or renal failure

### Intervention:
Comparisons of BNP values among diagnostic groups including HF and non HF pts

### Comparator:
Non-HF pts such as pulmonary disease, cor pulmonale

### 1st endpoint:
Diagnostic accuracy of BNP at a cutoff of 100 pg/mL was 83.4%. The negative predictive value of BNP <50 pg/mL was 96%.

### Secondary endpoint:
In multiple logistic-regression analysis, measurements of BNP added significant independent predictive power to other clinical variables in models predicting which pts had HF

- Used in conjunction with other clinical information, rapid measurement of BNP is useful in establishing or excluding the diagnosis of acute HF failure in pts with acute dyspnea

---

## van Kimmenade et al. 2006

### Aim:
To analyze the role of NT-pro-BNP in diagnosis of HF in acutely dyspneic pts from an international

### Inclusion criteria:
- Acutely dyspneic pts
- NT-pro-BNP concentrations, clinical characteristics, and 60-d mortality were studied in acutely dyspneic pts from an international

### Exclusion criteria:
- With trauma or cardiac tamponade, acute myocardial infarction, unstable angina, or renal failure

### Intervention:
Comparisons of NT-pro-BNP among diagnostic groups including HF and non-HF pts

### Comparator:
Non-HF pts such as pulmonary disease, cor pulmonale

### 1st endpoint:
Subjects with HF and diagnostically elevated NT-pro-BNP concentrations had the highest mortality rates, subjects without HF and NT-pro-BNP concentrations <300 ng/L had the lowest mortality rates, and subjects with gray-zone NT-pro-BNP had intermediate outcomes, irrespective of their final diagnoses.

- Adding specific clinical information to NT-pro-BNP improves diagnostic accuracy in subjects with intermediate NT-pro-BNP concentrations. Mortality rates in subjects with intermediate NT-pro-BNP concentrations are lower than in those with NT-pro-BNP concentrations diagnostic for HF but are higher than in subjects with NT-pro-BNP concentrations less than the gray zone
### Maisel et al. 2004 (25) 15364340

**Aim:** To examine the relationships among BNP levels and HF severity, clinical decision making, and outcomes

**Study type:** Multicenter, prospective, blinded, diagnostic accuracy study

**Size:** 464

**Inclusion criteria:** Pts over the age of 18 y presenting to the ED with HF and who received treatment in the ED or hospital admission for HF were included.

**Exclusion criteria:** Current MI or ACS with ST-segment deviation of ≥1 mm, renal failure requiring dialysis, or pts with a baseline BNP concentration of ≤100 pg/mL were excluded.

**Intervention:** Physicians were blinded to the actual BNP level and subsequent BNP measurements.

**Comparator:** Comparison between severity of HF determined by physicians or BNP and outcomes

**1st endpoint:** ED doctor's intention to admit or discharge a pt had no influence on 90-d outcomes, while the BNP level was a strong predictor of 90-d outcome. The 90-d combined event rate (HF visits or admissions and mortality) in the group of pts admitted with BNP <200 pg/mL and >200 pg/mL was 9% and 29%, respectively (p=0.006).

- In pts presenting to the ED with HF, there is a disconnect between the perceived severity of HF by ED physicians and severity as determined by BNP levels. The BNP levels can predict future outcomes and thus may aid physicians in making triage decisions about whether to admit or discharge pts. Emerging clinical data will help further refine biomarker-guided outpatient therapeutic and monitoring strategies involving BNP.

### O'Connor et al. 2010 (26) 20185037

**Aim:** To identify high-risk HF pts at hospital discharge

**Study type:** Predictive modeling using variables obtained during hospitalization in the ESCAPE trial

**Derivation cohort:** ESCAPE trial, n=423

**Validation cohort:** FIRST trial, n=471

**Inclusion criteria:** Hospitalized with severe HF, LVEF ≤30%, SBP ≤125 mmHg.

**Exclusion criteria:** Creatinine >3.5 mg/dL, prior inotrope use

**1st endpoint:**
- 6-mo mortality and death or rehospitalization rates (64%)
- Multivariate discharge predictors of death included: BNP, per doubling (HR: 1.42), cardiac arrest or mechanical ventilation, yes/no (HR: 2.54), BUN, per 20 mg/dL increase (HR: 1.22) and sodium, per unit mEq/L increase (HR: 0.93)

- A simplified discharge score discriminated mortality risk from 5% (score=0) to 94% (score=8).
- Bootstrap validation demonstrated good internal validation for the model (c-index 0.78).

- Limitations: ESCAPE represented pts with severe LV dysfunction and advanced symptoms (not the general population of acute HF) managed at experienced centers; exclusion of pts with characteristics...
**Data Supplement B. Nonrandomized Trials/ Observational Studies/ Registries for Changes in or Discharge NP Levels in ADHF – Biomarkers (Section 6.3)**

| Bayés-Genís et al. 2005 (27) 15948093 | Aim: Percentage of NT-proBNP reduction during admission and its prognostic significance  
Study type: NR  
Prospective cohort  
Size: 74 pts | Inclusion criteria: Pts diagnosed with acute HF in emergency department and who had follow-up evaluation for 6 & 12 mo after admission  
Follow up: 12 mo | 1st endpoints:  
- Percent reduction in NT-proBNP and its association with CV mortality  
Results:  
- The area under the ROC curve for % NT-proBNP reduction to predict CV death was 0.78 (95% CI: 0.66–0.90; p=0.002)  
- 30% NT-proBNP reduction percentage cutoff value had 75% accuracy for the identification of high-risk pts and was the only variable that was associated with CV death in multivariate analysis (OR: 4.4; 95% CI: 1.12–17.4; p=0.03).  
- Study relatively old and small |
| Verdiani et al. 2008 (28) 18545069 | Aim: To evaluate the prognostic significance of NT-proBNP % reduction during ADHF  
Study type: Prospective cohort  
Size: 120 pts | Inclusion criteria: Pts consecutively admitted with ADHF  
Follow up: 6 mo | 1st endpoint  
- Percent reduction in NT-proBNP and its association with CV mortality  
Results:  
- In ROC, the mean AUC for NT-ProBNP % reduction was 0.63 (95% CI: 0.51–0.75; p=0.04) for the composite endpoint (death or readmission), and 0.81 (95% CI: 0.65–0.97, p=0.01) for CV mortality at risk of events.  
- NT-ProBNP reduction percentage <30% was the best cut off for the identification of pts  
- Study relatively old and small |

### Clinical Assessment in Diagnosing HF

| Study type: Systematic review | **Inclusion criteria:** Study assessing incremental value of BNP or NT-proBNP for predicting morbidity and mortality in acute decompensated HF. **Exclusion criteria:** Studies of stable HF; natriuretic peptide could not be included in base model to allow assessment of incremental value. | **1º endpoint:** BNP or NT-proBNP improved prognostic model performance for mortality as assessed by discrimination and or likelihood statistics. **Results:** 5 BNP publications consistently predicted all-cause mortality in short (3–6 mo) and long (9,12 mo) beyond base model but not all statistically significant. Two NT-proBNP publications both showed incremental value at 22 mo and 6.8 y with 1 being statistically significant. | • Clinical heterogeneity precluded formal meta-analysis. |

| Study type: Systematic review | **Inclusion criteria:** Age >18 y presenting to ED or urgent care center with signs/symptoms suggestive acute HF. English language articles from 1989-2012. FDA-approved assays. **Exclusion criteria:** Studies with pts who had conditions that may impact NP levels (transplant, HCM, valvular) | **1º endpoint:** Test performance characteristics. **Results:** BNP pooled sensitivity=95%, 95% CI: 93–97%, specificity 67% (58–75%). NT-proBNP pooled sensitivity 91% (95% CI: 88–93), specificity 67% (50–80%). | • Both BNP and NT-proBNP had high sensitivity but low specificity. • Overall strength of evidence for sensitivity and all decision cutpoints for both peptides was high; strength of evidence for specificity rated as moderate. • Both BNP and NT-proBNP performed well to rule out, but less well to rule in, for the diagnosis of heart failure among patients presenting to the ED or urgent care centers. |

<p>| Study type: Diagnostic accuracy study (observational) | <strong>Inclusion criteria:</strong> Pts with new symptoms suggestive of HF referred by GP to rapid access HF clinics at 5 centers in UK between 2001 and 2003. | <strong>1º endpoint:</strong> Sensitivity, specificity, PPV, NPV, LR, AUC for diagnosis of HF. <strong>Results:</strong> 104 (34%) of pts had HF. | • 2 of 5 sites withdrew after recruiting 18 and 14 pts. • Both BNP and NT-proBNP are useful for ruling out HF in pts presenting to PCP with possible HF symptoms. |</p>

Zairis et al. 2010 (50) 19157603

Aim: To investigate the combined prognostic value of admission serum levels of BNP, cTnI and hs-CRP, in pts hospitalized because of acutely decompensated severe (NYHA class III/IV) low-output chronic HF.

Study type: Registry analysis

Size: 48,629

2004 entered into ADHERE were analyzed. BNP assessment on admission was performed in 48,629 (63%) of 77,467 hospitalization episodes

Exclusion criteria: Absence of BNP levels

risk of in-hospital mortality (OR: 2.09 and 2.41 respectively, each p<0.0001).

acutely decompensated HF.

Peacock et al. 2008 (51) 18480204

Aim: Describe the association between elevated cardiac troponin levels and adverse events in hospitalized pts with acute decompensated HF.

Study type: Registry analysis

Size: 48,629

2004 entered into ADHERE were analyzed. BNP assessment on admission was performed in 48,629 (63%) of 77,467 hospitalization episodes

Exclusion criteria: Absence of BNP levels

risk of in-hospital mortality (OR: 2.09 and 2.41 respectively, each p<0.0001).

acutely decompensated HF.

• In pts hospitalized for acute decompensation of severe (NYHA III/IV) low-output HF, BNP, cTnI and hs-CRP upon admission offers enhanced early risk stratification.

In pts with acute decompensated HF, a positive cardiac troponin test is associated with higher in-hospital mortality, independently of other predictive variables.

#### Dieplinger et al. 2010

(55) 20153308

**Aim:** To evaluate the prognostic value of established and novel biomarkers in pts with acute dyspnea

**Study type:** Observational

**Size:** 251

**Inclusion criteria:** Pts presenting to ED with acute dyspnea

**Exclusion criteria:** STEMI, NSTEMI or ACS troponin pos.

**Biomarkers:** BNP, MR-proANP, MR-proADM, copeptin, C-terminal pro-ET-1, soluble ST2, chromogranin A (CgA), adiponectin, proguanylin, prouroguanylin

**1° endpoint:** All-cause mortality at 1 y
- 25% died within 1 y
- At baseline, decedents (n=62) had higher median plasma concentrations of all 10 biomarkers than survivors (n=189)
- In multivariate model, only MR-proANP (RR: 1.6), ST2 (RR: 1.7) and CgA (RR: 1.5) were independent predictors of death
- Low systolic BP and advanced age were also independent predictors of 1-y mortality
- Limitations: post-hoc analysis; subgroup (87 of 251) had dyspnea due to acute HF alone; single-center, majority men (94%)

#### Ilva et al. 2008

(56) 18599345

**Aim:** To evaluate prevalence and prognostic significance of elevated cTnI and cTnT in acute HF

**Study type:** Observational substudy

**Size:** 364

**Inclusion criteria:** Hospitalized with acute HF

**Exclusion criteria:** ACS pts; missing sample for cardiac TnI/TnT

**Biomarkers on admission and 48 hours:** cTnT, cTnI, cystatin C, NT-proBNP

**1° endpoint:** 6-mo mortality
- 51% of pts had +cTnI and 30% had +cTnT
- 6-mo all-cause mortality was 18.7%
- Both cTnI (OR: 2.0; 95% CI: 1.2–3.5) and cTnT (OR: 2.6; 95% CI: 1.5–4.4) were associated with adverse outcome in pts with previous, but no de novo HF
- On multivariable analysis, cystatin C (OR: 6.3; 95% CI: 3.2–13), logNT-proBNP (OR: 1.4; 95% CI: 1.0–1.8) and SBP on admission (/10 mm Hg increase; OR: 0.9; 95% CI: 0.8–0.9) were independent risk predictors, whereas troponins were not
- Mortality was proportional to troponin release
- Limitations: exclusion of pts with ACS was based on clinician judgment; cut-off values for troponins was based on 2000 ESC/ACC guidelines

#### Januzzi et al. 2007

(57) 17692745

**Aim:** To examine the value of measuring ST2 in pts with acute dyspnea

**Inclusion criteria:** Pts presenting to ED with acute dyspnea

**1° endpoint:** death at 1 y
- ST2 levels were significantly higher in pts
- ST2 levels were higher in pts with HF/EF (0.67 ng/ml; IQR 0.31–1.50) vs. HFpEF (0.42 ng/ml; IQR 0.22–

**Aim:** To examine patient-specific characteristic of ST2 in pts with acute HF

**Biomarkers:** ST2, BNP, NT-proBNP, CRP
Aim: To determine the relationship between galectin-3 and cardiac structure and function in pts with acute dyspnea

Study type: Observational

Size: 115

Inclusion criteria: PT presenting to ED with acute dyspnea, detailed echo exams during admission

Exclusion criteria: N/A

Biomarkers: galectin-3, NT-proBNP

1° endpoint:
• Association between galectin-3 and echo and clinical indices
• Higher levels of galectin-3 associated with older age, poorer renal function, and higher NT-proBNP
• Significant relationship between galectin-3 and poorer RV function, higher RV systolic pressure and more severe MR and TR
• Galectin-3 levels higher in pts who died at 1 and 4 y
• In multivariate analysis, galectin-3 remained a significant predictor of 4-y mortality independent to echocardiographic markers of risk
• Limitations: delay between collection of biomarkers and echocardiograms; small, single-center cohort

Search Terms and Date: natriuretic peptides, heart failure, human, last 5 years. Last search done on April 18, 2016.

| **ONTARGET** Investigators et al. 2008 (63) 18378520 | **Aim:** Compare ACE (ramipril), ARB (telmisartan), and combination ACE/ARB in pts with CVD or high-risk DM  
**Study Type:** RCT  
**Size:** 25,620 | **Inclusion Criteria:** Pts >55 y of age, CAD, PVD, previous stroke, or high-risk DM with end-organ damage  
**Exclusion Criteria:** HF at trial entry, ACE or ARB intolerance, revascularization planned or <3 mo | **Intervention:** Run in, then randomization to ramipril (8,576) target dose 10 mg daily, telmisartan (8,542) target dose 80 mg daily or combination (8,502), titrated to BP | 1º endpoint:  
- Composite of CV death, MI, stroke, or HF hospitalization at 5 y  
Results: No difference in outcome (16.5% ACE, 16.7% ARB, 16.3% combination; CI: ARB RR: 1.01 (95% CI: 0.94–1.09)  
Compared to the ramipril arm:  
- Telmisartan had more hypotensive symptoms (p<0.001); less cough (p<0.001) and angioedema (p=0.01); same syncope.  
- Combination arm had more hypotensive symptoms (p<0.001); syncope (p=0.03); and renal dysfunction (p<0.001)  
- BP fell by 6.4/7.4/9.8 mm Hg  
- Less angioedema with telmisartan | |
| **TRANSCEND** Yusuf et al. 2008 (64) 18757085 | **Aim:** To assess the effectiveness of ARB in ACE-intolerant pts with CVD or high-risk DM  
**Study Type:** RCT  
**Size:** 5,926 | **Inclusion Criteria:** ACE-intolerant pts with CAD, PVD, previous stroke, or high-risk DM with end-organ damage  
**Exclusion Criteria:** HF at trial entry, ACE or ARB intolerance, revascularization planned or <3 mo | **Intervention:** Run in, then randomization to telmisartan titrated to 80 mg as tolerated (2,954)  
**Comparator:** Titration of other medications as needed to control BP (2,944) | 1º endpoint:  
- Composite of CV death, MI, stroke, or HF hospitalization at 5 y  
Results: No significant difference RR: 0.92 (95% CI: 0.81–1.05); p=0.216  
No difference in 2º outcomes; ARB was safe in this pt population - no angioedema | |
| **SUPPORT** Sakata et al. 2015 (65) 25637937 | **Aim:** Discover whether addition of ARB to ACE and beta blockers in pts with chronic HF will  
**Study Type:** RCT  
**Size:** | **Inclusion Criteria:** Pts 20–79 y of age with hypertension, NYHA class II-IV, stable on ACE ± beta blockers | **Intervention:** Randomization to olmesartan (578) titrated up to 40 mg as tolerated (578) (mean dose achieved at 5 y, 17.9) | 1º endpoint:  
- Composite of all-cause death, MI, stroke, or HF hospitalization at 4.4 y  
Results: No significant difference RR: 1.18 (95% CI: 0.96–1.46); p=0.11  
Pts on triple therapy with ACE/ARB/Beta blocker had more of 1º composite outcome, 38.1 vs. 28.2%, HR: 1.47 (95% CI: 1.11–1.95; p=0.006); all-cause death, 19.4 vs. 13.5%, HR: 1.50 (95% CI: 1.20–1.88) | |

| IMPRESS Rouleau et al. 2000 (68)      | Determine if inhibition of neutral endopeptidase and ACE with the vasopeptidase inhibitor omapatrilat is better than ACE inhibition alone with lisinopril | Inclusion criteria:  
- Informed consent  
- Age ≥18  
- Stable (>3 mo) symptomatic HF (NYHA class II–IV HF)  
- Decreased LVEF <40  
- ≥4 wk dose of ACE inhibitors  
- Seated SBP ≥90 mm Hg  
Exclusion criteria:  
- Uncontrolled hypertension  
- Acute coronary events within 3 mo  
- Revascularization within 3 mo  
- Serum potassium <3.5 or >5.3 mmol/L  
- Creatinine >221 mcmol/L  
- Transaminases >2 upper limit of normal  
- Leucocytes <3.0x10⁹/L, neutrophils <1.5x10⁹/L, or platelets <120x10⁹/L | Intervention: Omapatrilat (289) target dose 40 mg daily  
Comparator: Lisinopril (284) target dose 20 mg daily | 1° endpoint: Change in exercise duration from baseline to wk 12  
Results: Similar exercise duration at 12 wk (p=0.45) | No difference in combined endpoint of death and admission for worsening HF (p=0.52)  
- Combined endpoint of death and comorbidity for worsening HF was better for omapatrilat HR: 0.52 (95% CI: 0.28–0.96; p=0.035)  
- Angioedema occurred in no pts taking omapatrilat vs. 1 taking enalapril  
Comments: Vasopeptidase inhibitor omapatrilat did not improve exercise tolerance compared with ACE inhibitor lisinopril
### OVERTURE
**Packer et al. 2002 (69) 12186794**

**Aim:**
Determine dual ACE and NEP inhibitors provides greater benefit in pts with HF than ACE inhibitors alone

**Inclusion criteria:**
- NYHA class II–IV HF due to non/ischemic cardiomyopathy for ≥2 mo, or
- LVEF ≤30% and hospitalized for HF within 12 mo

**Exclusion criteria:**
- Surgically correctable or reversible cause of HF
- Likely to receive cardiac transplant or left ventricular assist device
- Severe 1° pulmonary, renal, or hepatic disease
- Hx of intolerance to ACE inhibitors
- ACS within 1 mo
- Coronary revascularization or an acute cerebral ischemic event within 3 mo
- Hx of ventricular tachycardia, ventricular fibrillation, or sudden death who did not have an ICD placed and had not fired within 2 mo
- Hx or hospitalization or intravenous therapy for HF within 48 h
- SBP >180 or <90 mm Hg
- Heart rate >130 bpm
- Serum creatinine >2.5 mg/dL
- Serum potassium <3.5 or >5.2 mmol/L

**Intervention:**
Omapatrilat (2,886), target dose 40 mg daily achieved 82.5%

**Comparator:**
Enalapril (2,884) target dose 10 mg BID achieved 86.4%

**1° endpoint:** Combined risk of death or hospitalization for HF requiring IV treatment

**Results:**
No significant difference HR: 0.94 (95% CI: 0.86–1.03; p=0.187)

**OCTAVE**
**Kostis et al. 2004 (70) 14751650**

**Aim:**
Compare safety and efficacy of dual ACE and NEP inhibitors to ACE inhibitors alone

**Inclusion criteria:**
- Age ≥18
- 3 separate BP criteria for 3 groups: Group 1 untreated hypertension (SBP ≥140 mm Hg or DBP ≥90 mm Hg); Group 2 hypertension and persistent mild hypertension (trough SBP 140–159 mm Hg and DBP <100 mm Hg, or trough DBP 90–99 mm Hg and SBP <160 mm Hg);

**Intervention:**
Omapatrilat target dose 80 mg daily

**Comparator:**
Enalapril target dose 40 mg daily

**1° endpoints:**
- Reduction in SBP at wk 8
- Need for new adjunctive antihypertensive therapy by wk 24

**2° endpoints:**
- Reduction in DBP at wk 8
- Reduction in SBP and DBP at wk 24
- BP control (SBP <140 mm Hg and DBP <90 mm Hg) at wk 8 and 24

© 2017 American College of Cardiology Foundation, the American Heart Association, Inc., and the Heart Failure Society of America.
Group 3 hypertension with persistent moderate to severe hypertension (trough SBP 160–179 mm Hg and DBP <110 mm Hg, or trough DBP 100–109 mm Hg and SBP <180 mm Hg)

**Exclusion criteria:**
- Contraindication to therapy with ACE inhibitors or angiotensin II receptor antagonists
- Hx of angioedema, anaphylaxis, drug-induced or chronic urticarial, or multiple drug sensitivities
- Recent hospitalization for MI, unstable angina, stroke, TIA or COPD
- Recent treatment for malignancy, chronic renal disease 2° to autoimmune disease, or end-stage renal disease of any etiology
- Hypertensive pts treated with ACE inhibitors whose BP placed them in study group 3

Greater reductions in BP in omapatrilat within each study (p<0.001)
- Overall mean reduction in SBP ≥3.6 mm Hg
- Larger reductions in BP in black pts with omapatrilat than with enalapril. But overall reduction smaller with both drugs than in other subgroups.
- Adverse events, serious adverse events, and deaths were the same for omapatrilat and enalapril
- More angioedema with omapatrilat (2.17% vs. 0.68%)
- More angioedema in blacks with omapatrilat (5.54% vs. 1.62%) and current smokers (3.93% vs. 0.81%)

---

<td><strong>Intervention:</strong> Ivabradine <strong>Comparator:</strong> Placebo</td>
<td><strong>1° endpoint:</strong> CV death or HF hospitalization rate increased with the comorbidity load (p&lt;0.0001) with most events in pts with &gt;3 comorbidities for both drug and placebo. Hospitalization rate lower for comorbidity loads of ivabradine</td>
<td>Number of comorbidities was related to outcomes Heart rate reduction with Ivabradine is conserved at all comorbidity loads</td>
</tr>
</tbody>
</table>
### SHIFT

**Aim:** To assess the effect of heart rate reduction by the selective sinus-node inhibitor ivabradine on outcomes in HF

**Study type:** randomized, double-blind placebo-controlled trial.

**Size:** 6,505

677 centers
37 countries

**Inclusion criteria:**
- Over 18 y of age, in sinus rhythm, resting heart rate of ≥70 bpm, stable symptomatic chronic HF (NYHA class II-IV) for ≥4 wk, previous admission to the hospital for HF within 12 mo, LVEF ≤35%

**Exclusion criteria:**
- HF due to congenital heart disease or 1° severe valvular disease. MI within 2 mo, ventricular or AV pacing for ≥40% of the d, AF or flutter, symptomatic hypotension

The following treatments not allowed during study:
- diltiazem and verapamil (nondihydropyridine CCB)
- class I antiarrhythmics
- strong inhibitors of CYP450 3A4

**Intervention:** Ivabradine

**Comparator:** Placebo

**1° endpoint:**
- Composite of CV death or hospital admission for worsening HF
  - Primary endpoint: ivabradine better. Event rate 24% vs. 29%. HR 0.82 (0.75–0.90); p<0.0001
  - Hospitalization for worsening HF: ivabradine better. 16% vs 21%, HR: 0.74 (95% CI: 0.66–0.83; p<0.001)
  - Death from HF: ivabradine better. 3% vs. 5%; HF: 0.74 (0.58–0.94); p=0.014

- Composite of CV death or hospital admission for worsening HF among those receiving at least 50% of target beta blocker dose at time of randomization. All cause death; any CV death; HF hospitalization; all-cause hospitalization; any CV hospitalization; death from HF, composite of CV death HF hospitalization, nonfatal MI.

- No difference in all-cause mortality or CV mortality

- Ivabradine better for all-cause hospitalization, HF hospitalization, CV hospitalization, and composite 2° endpoint

- Analyzed as time to first event. Median follow-up of 22.9 mo

- In subgroup analysis, effect limited to those with higher baseline heart rate (≥77 bpm)

- Use of devices was low (CRT in 1% and ICD in 4%)

- Mean age 61 y

- When added to GDEM, including beta blocker at optimal dose, ivabradine reduced adverse events, driven largely by HF mortality or HF hospitalization

**Adverse Effects:**
- 1% withdrew due to bradycardia (p<0.001)
- Phosphenes 3% (p<0.001)
- Comparable across age groups
- AF - ivabradine 9% vs. placebo 8% (p=0.012)

### SIGNIFY

**Aim:** Assess the mortality-morbidity

**Inclusion criteria:** Stable CAD without clinical HF and heart rate of ≥70

**Intervention:** Ivabradine (n=9,550)

**1° endpoint:**
- Composite of CV death and nonfatal MI

**Adverse Events:** Increased bradycardia, AF, phosphenes and cardiac disorders.

### SHEP HF Results

Kostis et al. 1997 (77) [9218667]

**Aim:** To assess the effect of antihypertensive treatment in isolated systolic HTN

**Study type:** RCT

**Size:** 4,736

**Inclusion criteria:**
- Age > 60
- SBP 160–219
- DBP < 90

**Exclusion criteria:**
- Recent MI or CABG
- pts with DM, stroke, AF

**Intervention:**
- Antihypertensive therapy: step 1, chlorthalidone, step 2, atenolol (2,365)

**Comparator:**
- Placebo (2,371)

**1° endpoint:**
- Incident HF
- Active treatment decreased BP from mean of 170/77 to mean of and decreased HF events from 105 (4.4%) with placebo to 55 (2.3%) RR: 0.51 (95% CI: 0.37–0.71, p<0.001) at 4.5 y

**2° results of SHEP showed decreased stroke risk with active treatment 149 (8.2%) with placebo to 96 (5.4%) RR: 0.64 (95% CI: 0.49–0.82, p=0.003) at 4.5 y**

**Limitations:** LV function was not measured

### CHARM-Preserved

Yusuf et al. 2003 (78) [13678871]

**Aim:** To ascertain efficacy of candesartan in pts with HFpEF.

**Study type:** RCT

**Size:** 3,023

**Inclusion criteria:**
- HF pts in NYHA class II-IV with EF >40%

**Exclusion criteria:**
- Creatinine > 265 μmol/L (3.0 mg/dL), potassium > 5.5 mmol/L, MI, stroke, or open-heart surgery in the previous 4 wk

**Intervention:**
- Candesartan (1,514)

**Comparator:**
- Placebo (1,509)

**1° endpoint:**
- CV death or admission for HF.
- No difference for candesartan 333 (22%) vs. placebo 366 (24%) at 3.5 y, HR: 0.92; 95% CI: 0.70–1.21; p=0.5.
- HF hospitalization lower at 1 y with perindopril: 34 events (8.0%) vs. placebo 53 (12.4%), HR: 0.63; 95% CI: 0.41–0.97; p=0.033).

**Limitations:** Many pts withdrew (40% by 18 mo), often to take open-label ACE inhibitors (36% by study end).

### PEP-CHF

Cleland et al. 2003 (79) [16963472]

**Aim:** To ascertain efficacy of perindopril in pts with HFpEF.

**Study type:** RCT

**Size:**

**Inclusion criteria:**
- Age ≥ 70, Rx with diuretics for clinical diagnosis of HF, echo criteria for diastolic dysfunction

**Exclusion criteria:**
- All-cause mortality or admission for HF.
- No difference for perindopril 107 (25.1%) vs. placebo 131 (23.6%) at 3 y, HR: 0.92; 95% CI: 0.70–1.21; p=0.5.

**Limitations:** Some pts may have had previous EF <40%.

### TOPCAT

**Pitt et al. 2014 (83)**

- New England Research Institutes
- Post-hoc analysis that captures differences in outcomes by geography - for reference list only

**Study type:** RCT

**Size:** 3,445

**Aim:** To assess the effects of spironolactone in pts with HFpEF.

**Inclusion criteria:**
- Symptomatic HF
- Age ≥50y, LVEF ≥45% stratified according to
- HF Hospitalization within past y
- Elevated NPs

**Exclusion criteria:**
- Renal disease (eGFR <30 or creatinine >22 μmol/L (2.5 mg/dL), systemic illness with life expectancy <3 y. Specific co-existing conditions, meds, and acute events

**Intervention:**
- Spironolactone (1,722)
- Comparator: Placebo (1,723)

**1° endpoint and results:**
- Composite of CV mortality, HF hospitalization, or aborted cardiac arrest.
- No difference with spironolactone vs. placebo
- 320 (18.6%) vs. 351 (20.4%), HR: 0.89; 95% CI: 0.77–1.04; p=0.138
- HF hospitalization was reduced with spironolactone 206 (12.0%) vs. 245 (14.2%), HR: 0.83; 95% CI: 0.69–0.99; p=0.04
- Increased hyperkalemia (18.7% vs. 9.1%), decreased hypokalemia (16.2% vs. 22.9%) and more doubling of creatinine (10.2% vs. 7.0%) with spironolactone
### TOPCAT Regional Analysis

**Aim:** To assess regional differences in the effects of spironolactone in pts with HFpEF.

**Study type:** RCT

**Size:** 3,445

**Inclusion criteria:**
- Symptomatic HF
- Age ≥50y, LVEF ≥45% stratified according to
  - HF Hospitalization within past y
  - Elevated NPs

**Exclusion criteria:**
- Renal disease (eGFR <30 or creatinine >22 μmol/L (2.5 mg/dL), systemic illness with life expectancy <3 y. Specific co-existing conditions, meds, and acute events

**Intervention:** Spironolactone (1,722)

**Comparator:** Placebo (1,723)

**1° endpoint and results:**
- Composite of CV mortality, HF hospitalization, or aborted cardiac arrest across regions.
- 1° outcome events in 522 (29.5%) pts in the Americas and 149 (8.9%) in Russia/Georgia. 1° outcome event rates with spironolactone and placebo 10.4/100 pt y and 12.6/100 pt y in the Americas and 2.5/100 pt y and 2.3/100 pt y in Russia/Georgia. HR spironolactone vs. placebo 0.82; 95% CI: 0.69–0.98; p=0.026) in the Americas and 1.10 95% CI: 0.79–1.51; p=0.12) in Russia/Georgia.

- Spironolactone had markedly greater effects on BP (4.2 mm Hg drop vs. 0.6 mm Hg; p<0.001, potassium change relative to placebo (0.26 mmol/L vs. 0.08 mmol/L), and increase in creatinine (0.10 vs. 0.02 mg/dL; p<0.001)

**Limitations:** post-hoc analysis

---

### Chen et al. 2015

**Aim:** To assess effects of MRAs in pts with HFpEF.

**Study type:** Meta-analysis

**Size:** 14 RCTs with 6,428 pts

**Inclusion criteria:**
- Prospective, RCTs that enrolled adult pts with LVEF ≥40% (including post-MI and those with symptomatic or asymptomatic HF) with a study duration of ≥4 mo that assessed at least 1 clinical outcome of interest.

**Intervention:** MRAs (3,249)

**Comparator:** Placebo (2,861) Or standard therapy (301) Or active comparator (31)

**1° endpoint and results:**
- All-cause mortality and HF hospitalization
- No difference in all-cause mortality (RR: MRAs vs. placebo 0.90; 95% CI: 0.78–1.04; p=0.17)
- Reduced risk of HF hospitalization (RR: MRA vs. placebo 0.83; 95% CI: 0.70–0.98; p=0.03)

**1° Safety endpoint :**
- More hyperkalemia with MRAs (12.2% vs. 6.2%, p<0.001)

- MRAs improved QOL (weighted mean difference −5.2; 95% CI: −8.0–−2.3).
- MRA’s improved echo indices of LV function: E/e’, E/A ratio, deceleration time, interventricular relaxation time
- Renal failure in 1.19% of pts with MRAs vs. 0.39%
- Gynecomastia in 2.81%R vs. 0.3%

**Limitations:** discrepancies in definitions of HFpEF in different trials; heterogeneity of trial outcomes and their assessment, including follow-up duration; 1° outcome results driven by
Aim: To address safety and efficacy of LCZ696 in pts with HFpEF.

Study type: RCT

Size: 308

Inclusion criteria:
Pts ≥40 y of age, LVEF ≥45%, NYHA class II-III HF, NT-pro BNP >400 pg/mL

Exclusion criteria:
Previous EF <45%, isolated right HF, noncardiac dyspnea, CAD or CVD needed revascularization <3 mo Right HF due to pulmonary disease, dyspnea due to noncardiac causes, valvular/myocardial disease, CAD or CVD needing revascularization within 3 mo of screening.

Intervention: LCZ696 (149)

Comparator: Valsartan (152)

1° endpoint:
• Change in BNP at 12 wk
• Greater reduction with LCZ696 (ratio of change compared to valsartan 0.77; 95% CI: 0.64–0.92; p=0.001)

1° Safety endpoint:
• Serious adverse events 15% in LCZ676 group and 20% in valsartan group (p=NS)

Date: Some studies added by chairs in December 2015, others added by the writing committee.

**CONFIRM-HF**

**Aim:** To assess benefits and safety of long-term FCM in iron-deficient pts with HF

**Study type:** RCT (1:1)

**Size:** 304

**Inclusion criteria:**
- Pts at least 18 y, NYHA class II or III, LVEF ≤ 45%, elevated NPs, ID defined as ferritin <100 ng/mL, or ferritin 100–300 ng/mL if TSAT <20%, Hb <15 mg/dL

**Exclusion criteria:**
- Pts in need of transfusion, if not able to complete 6MWT, uncontrolled HTN, infection, malignancy, impaired liver or renal function

**Intervention:**
- FCM (152)

**Comparator:**
- Placebo (152)

**1° endpoint:**
- Change in 6MWT distance from BL to wk 24

**2° Endpoints:**
- Changes in NYHA class
- PGA
- 6MWT distance
- Fatigue score
- KCCQ
- EQ-5D
- Assessed at wk 6, 12, 24, 36, 52
- Rate of any hospitalization, rate of hospitalization for any CV reason, and rate of hospitalization due to worsening HF;
- Time to first hospitalization for any reason, time to first hospitalization for any CV reason and time to first hospitalization due to worsening HF;
- Time to death for any reason, time to death for any CV reason, and time to death due to worsening HF.

**Results:**
- Significant improvements in NYHA class, PGA, QoL and Fatigue scores, 6 MWD up to 52 wk
- Significant reduction in the risk of hospitalizations for deteriorating HF, HR: 0.39 (95% CI: 0.19–0.82) (p=0.009)
- Preserved treatment effect across subgroups
- No differences in adverse events when compared to placebo
- Study was not designed to test morbidity and mortality outcomes of the ID therapy with FCM

<tr>
<td>Xie et al. 2016 (89) 26559744</td>
<td>Aim: To assess the efficacy and safety of intensive BP lowering strategies. Study Type: SR and meta-analysis. Size: 19 trials with 44,989 pts; 3.8 y of follow-up. Inclusion Criteria: RCTs with different BP targets or different BP changes between more vs. less intense therapy with at least 6 mo follow-up. Exclusion Criteria: Trials that did not assess a different target or relevant outcome.</td>
<td>5 RCTs (6,960 pts) enrolled only pts with DM and 6 trials (2,809 pts) specifically recruited pts with CKD.</td>
<td>1st Outcomes: Major CV events, defined as MI, stroke, HF or CV death, separately and combined; nonvascular and all-cause mortality; ESRD; and adverse events; new onset microalbuminuria/macroubuminuria or change from micro- to macroalbuminuria and retinopathy in pts with DM. Results: Pts in the more intensive BP-lowering treatment group had mean BP 133/76 mm Hg compared with 140/81 mm Hg in the less intensive group. Intensive BP-lowering treatment achieved RR reductions for major CV events: 14% (95% CI: 4, 22), MI: 13% (95% CI: 0, 24), stroke: 22% (95% CI: 10, 32), albuminuria: 10% (95% CI: 3, 16), and retinopathy progression: 19% (95% CI: 0–34). However, more</td>
<td>Study Limitations: Only 6,960 pts with DM were included in the total study size of 44,989 pts. Conclusions: The absolute CV benefits were greatest in trials in which all enrolled pts had vascular disease, renal disease or DM. However, only 6,960 of the 44,989 pts had DM and no subanalysis for DM was provided; however, the outcome benefits were qualitatively most striking for pts with DM, CKD and/or vascular disease.</td>
<td></td>
</tr>
</tbody>
</table>
### SPRINT
**Aim:** To test the effectiveness of a goal SBP <120 mm Hg vs. a goal SBP <140 mm Hg for the prevention of CVD in pts with SBP ≥130 mm Hg at BL.

**Study type:**
- SBP ≥130 mm Hg, with upper limit varying as number of pre-trial BP-lowering meds increased. Age ≥50 y Presence of at least 1:
  - Clinical or subclinical CVD

**Inclusion criteria:**
- SBP ≥130 mm Hg, with upper limit varying as number of pre-trial BP-lowering meds increased. Age ≥50 y Presence of at least 1:
  - Clinical or subclinical CVD

**Intervention:**
- Intensive BP lowering treatment to goal SBP <120 mm Hg (4,678)
- Standard BP lowering treatment to goal SBP <140 mm Hg (4,678)

**Comparison:**
- Composite of MI, non-MI ACS, stroke, ADHF, CV death; HR: 0.75 (95% CI: 0.64, 0.89)
- Lower BP target reduced composite outcome 243 pts (1.65%/y) vs. higher target 319 (2.19%/y), HR: 0.75; 95% CI: 0.64–0.89; p<0.001 and death: lower target 155 vs. 201, HR: 0.73; 95% CI: 0.60–0.90;

**1st Endpoint:**
- More intensive SBP lowering to a goal of <120 mm Hg with achieved mean of ~121 mm Hg resulted in less CVD and lower total mortality over 3.26 y in comparison with a goal SBP <140 mm Hg and achieved SBP of ~135 mm Hg.
- There were small increases in some expected SAEs. Perhaps unexpected, a sizable increase

**Summary:**
- More intensive SBP lowering to a goal of <120 mm Hg with achieved mean of ~121 mm Hg resulted in less CVD and lower total mortality over 3.26 y in comparison with a goal SBP <140 mm Hg and achieved SBP of ~135 mm Hg.
- There were small increases in some expected SAEs. Perhaps unexpected, a sizable increase.
### RCT

**Size:**
- 9361 pts followed
- median of 3.26 y.

**Exclusion criteria:**
- CKD stage 3 or greater
- Age ≥75
- Framingham General CVD risk ≥15% in 10 y

During the trial, mean SBP was 121.5 vs. 134.6.

<table>
<thead>
<tr>
<th>Other endpoints:</th>

</thead>
<tbody>
<tr>
<td>Total deaths HR: 0.73 (95% CI: 0.60–0.90)</td>
</tr>
<tr>
<td>1° or death HR: 0.78 (95% CI: 0.67–0.90)</td>
</tr>
<tr>
<td>Components of 1° composite mostly consistent in direction other than ACS – no difference.</td>
</tr>
</tbody>
</table>

**CKD outcomes:**
- 1° in CKD pts: reduction in GFR of ≥50% or ESRD HR: 0.89 (95% CI: 0.42, 1.87)
- Incident albuminuria HR: 0.72 (95% 0.48, 1.07)
- In pts without CKD: reduction in GFR ≥30% and to <60 HR: 3.49 (95% CI: 2.44–5.10)
- Incident albuminuria HR: 0.81 (95% CI: 0.63–1.04)

**Adverse events:**
- SAEs: 1.04, p=0.25
- Significant absolute increases seen in intensive group for hypotension (1%), syncope (0.6%), electrolyte abnormality (0.8%), AKI/ARF (1.6%) over the study period.
- 1.7% fewer pts had orthostatic hypotension in intensive group, p=0.01.

### Limitations:
- Few pts were untreated at BL ~9%, so SPRINT provides little if any insight at present regarding BP lowering medication initiation for untreated people with SBP 130–139.

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1&lt;sup&gt;st&lt;/sup&gt; endpoint:</td>
<td>CAD events; stroke</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Results:</td>
<td>In 37 trials of pts with a history of CAD, beta blockers reduced CAD events 29% (95% CI: 22%–34%). In 27 trials in which beta blockers were used after acute MI, beta blockers reduced CAD events 31% (95% CI: 24%–38%), and in 11 trials in which beta blockers were used after long term CAD, beta blockers insignificantly reduced CAD events 13%. In 7 trials, beta blockers reduced stroke 17% (95% CI: 1%–30%). CAD events were reduced 14% (95% CI: 2%–25%) in 11 trials of thiazide diuretics, 17% (95% CI: 11%–22%) in 21 trials of ACE inhibitors, insignificantly 14% in 4 trials of angiotensin receptor blockers, and 15% (95% CI: 8%–22%) in 22 trials of CCBs. Stroke was reduced 38% (95% CI: 28%–47%) in 10</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

• With the exception of the extra protective effect of beta blockers given shortly after a MI and the minor additional effect of CCBs in preventing stroke, all the classes of BP lowering drugs have a similar effect in reducing CAD events and stroke for a given reduction in BP.

### Sites:
176 national sites that w/ provider & geographic heterogeneity

### Inclusion criteria:
- Chronic HF (defined as ≥12 wk since diagnosis) according to current ESC guidelines
- LVEF ≤45%
- Hypopnea index of ≥10/h
- Stable, GDMT
- NYHA class III or IV, or NYHA class II with ≥1 hospitalization for HF in the last 24 mo
- No hospitalization for HF in 4 wk prior to enrolment

### Intervention:
Adaptive servo-ventilation use ≥5h/night, 7d/wk. (n=666)

### Comparator:
GDMT (n=659)

### 1st endpoint:
- Death from any cause
- Lifesaving CV intervention (cardiac transplantation, implantation of a ventricular assist device, resuscitation after sudden cardiac arrest, or appropriate lifesaving shock) or
- Unplanned hospitalization for HF

### Significant Results
- All-cause mortality was higher with the intervention (34.8%) than

### 2nd Endpoint
- CV death
- Unplanned hospitalization from any cause
- Time to death from CV causes
- Change in NYHA class
- Change in 6-MWT (both at follow-up visits).
- General QoL (EuroQOL)
- HF-specific QoL (MLWHF)
- Daytime sleepiness
### 2017 Heart Failure Focused Update Data Supplement

**Table:**

<table>
<thead>
<tr>
<th>1,325</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Optimized GDMT</td>
</tr>
<tr>
<td>• No new class of disease-modifying drug for prior ≥4 wk</td>
</tr>
<tr>
<td>• AHI &gt;15/h with ≥50% central events and a central AHI ≥10/h</td>
</tr>
</tbody>
</table>

**Exclusion criteria:**

- Significant COPD with a forced expiratory volume in 1 s in 4 wk before randomization
- O₂ saturation ≤90% at rest during d
- Currently receiving PAP therapy
- Cardiac surgery, PCI, MI or UA within the previous 6 mo
- Cardiac resynchronization therapy implantation scheduled or performed within 6 mo prior to randomization
- TIA or stroke within the previous 3 mo
- 1° hemodynamically-significant uncorrected VHD (obstructive or regurgitant) or any valvular disease expected to require surgery during the trial;
- Acute myocarditis/pericarditis within the previous 6 mo
- Untreated or therapy-refractory restless legs syndrome
- Contraindications to the use of AutoSet CS2 because of symptomatic hypotension or significant intravascular volume depletion or pneumothorax or pneumomediastinum
- Pregnancy

**Control:**

- (29.3%; HR: 1.28; 95% CI: 1.06–1.55; p=0.01).
- CV mortality was higher with the intervention (29.9%) than control (24.0%; HR: 1.34; 95% CI: 1.09–1.65; p=0.006).
- 6MWT decreased over time and were significantly lower with the intervention than with the control (p=0.02).
- Daytime sleepiness decreased over time and was significantly lower with the intervention than with the control (p<0.001).

**Non-Significant Results**

- Unplanned hospitalization for HF was not significantly higher with the intervention (43.1%) than control (41.3%; HR: 1.13; 95% CI: 0.95–1.33; p=0.16)
- Of the lifesaving CV interventions, none were significantly higher with the intervention than control (p=0.08–0.61)
- Unplanned hospitalization for any cause was not significantly lower with the intervention (67.9%) than control (66.0%; HR: 1.05; 95% CI: 0.92–1.20; p=0.47)
- The NYHA class change was not significantly different with the intervention than with the control (p=0.46)
- General QoL trends were not significantly higher with the intervention than with the control (p=0.09).
- HF-specific QoL trends were not significantly higher with the

**Limitations:**

- Unblinded study - more likely to favor treatment group, particularly for QOL, but no QOL improvement seen
- HF pts with reduced EF only
- HF pts with predominantly CSA not obstructive sleep apnea.
- Sample had very limited # of women but reflects epidemiology of CSA with HF/EF

### CPAP for CSA & HF (CANPAP)

**Aim:**
Test long-term treatment of CSA w/ CPAP in HF pts receiving optimal medical therapy on combined rates of death & ht tx.

**Study type:** 11 center RCT

**Size:** 258

**Inclusion criteria:**
- 18-79 y
- NYHA II-IV
- HF due to ischemia
- HTN, Idiopathic DCM
- Stable condition
- Optimal medical therapy for 1+ mon
- LVEF <40%
- CSA w/ ≥15 AHI >50% of AHI had to be central.

**Exclusion criteria:**
- Pregnancy
- MI
- UA
- Cardiac surgery within prior 3 mon, OSA

**Intervention:**
CPAP n=128

**Comparator:** No CPAP n=130

1° endpoint:
Transplant free survival

No significant difference in transplant free survival between CPAP and control groups (p=0.54)

2° endpoints:
- Hospitalizations
- EF
- Frequency of apnea and hypopnea episodes
- Mean nocturnal SaO2
- 6MWT
- QoL
- Neurohormones – norepinephrine and atrial NP

**Limitations:**
- Underpowered because trial stopped early for low enrollment

- LVEF significantly increased over time in CPAP-suppressed group (p<0.001)
- LVEF significantly increased in CPAP-suppressed vs. CPAP-unsuppressed (p=0.006) and vs. control (p<0.001) groups.
- No significant difference between CPAP-unsuppressed and control group (p=0.984)

#### Significant Results

**1° endpoint:**
- **LVEF**: Significant improvement in CPAP group (p<0.001) and vs. control group (p=0.04)
- **Overnight urinary norepinephrine excretion**: Significant reduction in CPAP group (p<0.05) and vs. control group (p=0.036)
- **BP**: No significant difference in CPAP group or between groups
- **QoL**: Significant improvements in most domains within CPAP group
- **SF-36**: Significant improvements between groups in 4/8 domains
  - Physical (p=0.03)
  - Vitality (p=0.02)
  - Social (p=0.03)
  - Mental health (p=0.01)

<table>

<td>• Epworth sleepiness scale</td>
</tr>
<tr>
<td>• BMI</td>
</tr>
<tr>
<td>• AHl events per h</td>
</tr>
<tr>
<td>• Minimum SpO2 saturation</td>
</tr>
</tbody>
</table>

#### Limitations:
- No placebo
- Significant difference between groups in peak Vo2 and mean BP at BL
- Dropout rate = 27%
- Higher than expected death rate
- Higher than expected rate of interventions initiated that may have effected end points
- Small sample size with only 3 females
